This report summarizes the uses of water in Wisconsin during 1979. It considers all uses except those not involving significant position movement such as recreation. The greatest single use of water, an instream use, was for hydroelectric power production. About 26 trillion gallons, or 93% was used for this purpose. Of the other 7% where water is pumped to a different location 81% (6% of all water use) was cooling water for thermoelectric powerplants. Withdrawals of surface water by public and private systems are for residential, industrial, commercial, irrigation, and stock uses. (USGS)

HYDROLOGIC DATA FROM MONITORING OF SALINE-WATER INTRUSION IN THE CAPE CORAL AREA, LEE COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
D. J. Fitzpatrick.
Available from the OFSS, USGS, Lakewood CO 80225, Price: $6.75 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-772, 48 p, 19 Fig, 7 Tab, 2 Ref.

Descriptors: Aquifers, Water levels, Water quality, Observation wells, Lithology, *Saline water intrusion, *Florida, Lee County, Cape Coral, *Hydrologic data.

As a result of declining water levels and saltwater intrusion in the Cape Coral area, the U.S. Geological Survey, in cooperation with the City of Cape Coral, established a monitor well network in Cape Coral and adjacent areas in 1978. The network was designed to monitor water levels and water quality, to collect background data from water-bearing zones in the upper and lower parts of the Hawthorn Formation, the upper part of the Tampa Formation, and the surficial aquifer. A network of 34 wells tapping the artesian freshwater-bearing aquifer in the upper part of the Hawthorn Formation was established, and water-quality samples were collected and analyzed semiannually from 1978-80. Water levels in selected wells were monitored continuously or measured monthly, bimonthly, or semiannually for general trends. Thirty-six wells tapping the surficial and six wells tapping the artesian aquifer in the lower part of the Hawthorn Formation were constructed. Selected wells in these aquifers have also been monitored for water levels continuously, or at monthly, bimonthly, or semiannual intervals. Water-quality data were collected from selected wells for background information. Lithologic logs were prepared for 18 wells penetrating one or more of the three aquifers. (USGS)

This report provides: (1) r 788 selected wells and test holes in- cation, construction, water use, water oride concentration, specific conduc- perature, yield, hydrogen sulfide, and g problems; and (2) lithologic logs for es ranging in depth from 90 to 650 feet. entoried wells and two test holes are in parts of Collier or Glades Counties.

OGIC DATA FOR THE PELICAN NDS AQUIFER, WESTERN MINNE-
Survey, St. Paul, MN. Water Re- v.
r.
n-File Report 80-695, 1981. 86 p, 2 Fig, f.

s: *Groundwater, *Observation wells, vels, *Water quality, Aquifer, Draw- down, Data collections, Pump testing, *Basic data, *Pelican River, *Minnesota.

Hydrogeologic data for the Pelican River sands aquifer have been compiled in this report for use by the public and by State and local officials in making water development and management decisions. This report will supplement an interpretive report on the hydrogeology of the Pelican River sands aquifer that is scheduled for publication in 1981. The data which were collected in 1965, 1972, and 1978-79, include results of chemical analyses of water from selected wells, water-level measurements in wells, logs of test holes and observation wells, and results of aquifer tests. DRAINAGE AREAS OF THE KANAWHA RIVER BASIN,
Geological Survey, Charleston, WV. Water Resources Div.
M. V. Mathes, D. D. Payne, Jr., and R. A. Shultz.
USGS Open-File Report 82-351, 1982. 222 p, 1 Fig, 2 Tab, 1 Ref.

Descriptors: *Drainage area, *River miles, *Data collection, *West Virginia, Kanawha River basin, *Data collection.

Drainage areas for 1,493 drainage area divisions for the Kanawha River basin, West Virginia, are listed in the report. Also tabulated for each site are river miles, plus location identifiers: County, latitude and longitude, and the West Virginia District map number. (USGS) W84-00948

POTENTIOMETRIC-SURFACE MAP OF WATER IN THE EAGLE SANDSTONE AND EQUIVALENT UNITS IN THE NORTHERN GREAT PLAINS AREA OF MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
G. W. Levings.
USGS Open-File Report 82-565, 1982. 1 Sheet map, 1 Fig, 7 Ref.

Descriptors: *Groundwater, *Potentiometric level, *Aquifers, Eagle Sandstone, Virgelle Sandstone, Telegraph Creek Formation, *Montana, *Maps.

The potentiometric surface of water in the Upper Cretaceous Eagle Sandstone and equivalent units (Virgelle Sandstone and Telegraph Creek Formation) is shown on a base map at a scale of 1:1,000,000. The map is one of a series of maps produced as part of a regional study of aquifers of Cenozoic and Mesozoic age in the northern Great plains of Montana. The contour interval is 200 feet. The map shows that the directions of regional ground-water movement is from west to east except in the extreme northwestern corner where the movement is from east to west. Water is discharged from the Eagle Sandstone to the Missouri River south of the Bearpaw Mountains. In the area north of the Bearpaw Mountains, depressurization from gas production may account for the decline in the potentiometric surface. The average discharge from 115 wells is about 23 gallons per minute and the specific capacity of 85 wells averages 1.4 gallons per minute per foot of drawdown. (USGS) W84-00949

GROUND-WATER LEVELS IN WYOMING, 1971 THROUGH PART OF 1980,
Geological Survey, Cheyenne, WY. Water Resources Div.
J. O. Ragsdale.
USGS Open-File Report 82-859, 1982. 200 p, 171 Fig, 21 Tab, 7 Ref.

Descriptors: *Groundwater, Hydrographs, *Observations wells, Water-level recorders, *Wyoming, Cheyenne, Data collections.

Ground-water levels are measured periodically in a network of about 280 observation wells in Wyoming, mostly in areas where ground water is used in large quantities for irrigation or municipal purposes. The program is conducted by the U.S. Geological Survey in cooperation with the Wyoming State Engineer and the city of Cheyenne. This report contains maps showing the locations of selected wells, tables listing well histories and highest and lowest water levels for the period of record, and hydrographs for most of the wells. (USGS) W84-00950

DATA ON SUBSURFACE STORAGE OF LIQUID WASTE NEAR PENSACOLA, FLORIDA, 1963-1980,
Geological Survey, Tallahassee, FL. Water Resources Div.
R. W. Hull, and J. B. Martin.
USGS, OFSS, Fed. Cntr., Lakewood, CO. 80225, Price: $24.00 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-689, 1982. 179 p, 10 Fig, 31 Tab, 40 Ref.

Descriptors: *Injection wells, *Underground waste disposal, Monitoring, Underground storage, Data collections, *Florida, *On-site monitoring wells, Facilities monitoring.

Since 1963, when industrial waste was first injected into the subsurface in northwest Florida, considerable data have been collected relating to the geochemistry of subsurface waste storage. This report presents hydrogeologic data on two subsurface waste storage. This report presents hydrogeologic data on two subsurface storage systems near Pensacola, Fla., which inject liquid industrial waste through deep wells into a saline aquifer. Injection sites are described giving a history of well construction, injection, and testing; geologic data from cores and grab samples; hydrographs of injection rates, volume, pressure, and water levels; and chemical and physical data from water-quality samples collected from injection and monitor wells. WATER RESOURCES OF THE GUYANDOTTE RIVER BASIN, WEST VIRGINIA,
Geological Survey, Charleston, WV. Water Resources Div.
J. S. Bader, J. L. Chisholm, R. L. Bragg, and S. C. Downs.
West Virginia Geological and Economic Survey, Morgantown, Basic Data Report No 7, 1977. 550 p, 58 Fig, 13 Tab, 632 Ref.

Descriptors: *Flow characteristics, *Surface runoff, Geology, Surface-ground water relationships, *Chemical analyses, *Aquatic microbiology, *Waste disposal, Streamflow, Water quality, Water-pollution sources, Conductivity, *West Virginia, *Guyandotte River basin, 7-day, 10-year flow, *Well yield, Geologic structure, Coal-mining activities.

The 1975-78 water-resources study of the Guyandotte River basin, West Virginia is part of the continuing investigation of the water resources of the State's basins by the U.S. Geological Survey. The study, conducted in cooperation with the West Virginia Geological and Economic Survey and the West Virginia Department of Natural Resources, Division of Water Resources, includes an inventory of available water, water quality, and occurrence. Surface-water-runoff characteristics such as average runoff per year, 7-day 10-year flow, mean-annual streamflow, maximum flood discharge, and time of travel are described. An interpretive description of surface water quality, basin on chemical, biological, microbiological, and physical data collected at some 140 stream sites, is presented. Both the quantity and quality of ground water are related to control factors. The most important factors affecting well yields are shown to be geologic and topographic structure. Potential and existing water-quality problems, as related to ground water and surface water, are pointed out. (USGS) W84-00952

JANUARY 1982 WATER LEVELS, AND DATA RELATED TO WATER-LEVEL CHANGES, WESTERN AND SOUTH-CENTRAL KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
M. E. Pabst
Available from the USGS, OFSS, Fed. Center, Lakewood, CO 80225, Price: $21.50 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-649, 1982. 167 p, 2 Fig 1 Tab, 13 Ref.

Descriptors: *Groundwater, *Water-level changes, *Hydrologic data, *Kansas, Base-line studies.

Water-level measurements were made, mostly in January 1982, in about 1,530 wells in western and south-central Kansas. The measurements were made in mid-winter when pumping was minimal and water levels had recovered, for the most part, from the effects of pumping during the previous irrigation season. Annual hydrologic data are provided for relating water-level changes from a 'base-reference year' (predevelopment year), a year of abnormally high rainfall and minimum pumpage (1966 or 1974), and each of seven consecutive years of measurement (1976-82), the 'base-reference year' is designated as 1940 for the southwestern area, 1944 for the south-central area, and 1950 for the northwestern and west-central areas. Water levels for the 'base-reference year' are established by measurements made during that year and by interpretation of maps showing water-level altitudes. Data also are provided for relating the average annual water-level changes, saturated thicknesses of the deposits, and percentage changes in saturated thicknesses. (USGS)

QUALITY OF RUNOFF FROM SMALL WATERSHEDS IN THE TWIN CITIES METROPOLITAN AREA, MINNESOTA--HYDROLOGIC DATA FOR 1980,
Geological Survey, St. Paul, MN. Water Resources Div.
G. A. Payne, M. A. Ayers, and R. G. Brown.
Available from the USGS, OFSS, Lakewood CO 80225, Price: $37.75 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-504, 1982. 289 p, 7 Fig, 17 Ref.

Descriptors: *Storm runoff, *Urban runoff, *Agricultural runoff, *Small watersheds, Urban hydrology, Land use, Storm water, Storm drains, Precipitation(Atmospheric), Antecedent precipitation, Rainfall intensity, Rain gages, Water quality, Twin Cities metropolitan area, *Minnesota.

An investigation of nonpoint-source runoff from small watersheds in the Twin Cities metropolitan area was conducted to define relationships between land use, watershed characteristics, and the quantity, quality, and timing of runoff. Six rural and four urban watersheds ranging in size from 1.22 to 82.9 square miles were studied. Discharge and water-quality data were collected at 19 sites during 1980. Recording instruments and automatic samplers provided continuous discharge records at 17 sites, continuous rainfall records and automatic collection of samples at 12 sites, and wetfall/dryfall precipitation samples at six sites. Sampling was intensified during periods of increased runoff resulting from snowmelt and rainstorms. Primary emphasis was placed on analysis of samples for suspended solids, nutrients, and chemical oxygen demand. Samples were also analyzed for chloride, metals, bacteria, and pesticides. The data are documented in tables containing basin characteristics and land use, daily and unit values for discharge and rainfall, rainfall characteristics, water-quality data for runoff and precipitation, results of laboratory settling test, results of quality assurance tests, daily loads, and storm loads. PRINCIPAL AQUIFERS IN FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. Franks, J. Cushman-Roisin, J. A. Miller, C. B. Bentley, and H. Klein.
USGS Water-Resources Investigations Open-File Report 82-255, 1982. 4 Sheet Maps, 15 Fig, 7 Tab, 160 Ref.

Descriptors: *Groundwater, *Aquifers, Geohydrology, Unconsolidated aquifers, Coastal aquifers, Water aquifers, Water supply, Groundwater availability, *Maps, *Florida.

Ground water, readily available throughout most of Florida, is the primary source of drinking water for about 90% of the State's population. The State has several ground-water reservoirs that yield large quantities of water to wells, and also has some of the world's largest springs. Virtually all of Florida is underlain by underground sources of drinking water capable of yielding at least small quantities of water to wells. The principal source of ground water is the Floridan aquifer, which supplies most of the water used in the State. The Biscayne aquifer of southeast Florida, although limited in areal extent compared to the Floridan aquifer, is also a major source of ground water. Other principal aquifers are the sand-and-gravel aquifer of the western panhandle, and smaller, surficial and intermediate depth aquifers located beneath much of coastal and southern Florida. (USGS)

USGS Map Series No 104, 1982. 1 Sheet Map, 3 Fig, 17 Ref.

Descriptors: *Groundwater, Confined aquifers, *Maps, *Florida, Floridan aquifer, *Potentiometric surface.

The contours depicting the potentiometric surface of the Floridan aquifer for May 1980 were prepared from water levels measured in 1,818 wells. Comparison of the May 1980 potentiometric surface with that of July 1961 shows that the potentiometric surface has not changed appreciably from 1961 to 1980 except in areas of heavy withdrawals. Declines of the potentiometric surface, as shown by a map and hydrographs, range from less than 10 feet throughout most of the State to more than 20 feet in the northwest panhandle (Okaloosa County) and in west-central peninsular Florid (Polk County). SELECTED FLOW CHARACTERISTICS OF FLORIDA STREAMS AND CANALS,
Geological Survey, Tallahassee, FL. Water Resources Div.
D. W. Foose.
USGS Water-Resources Investigations Report 83-4107, 1983. 265 p, 19 Fig, 1 Tab, 4 Ref.

Descriptors: *Low-flow frequency, *Duration table, *Hydrograph, Surface water, *Florida.

Data and statistics on low-flow frequency for 254 stream-gaging stations on Florida streams and canals are presented. The selected stations have 10 or more years of continuous record. A site description, a 10-year hydrograph, and a table of flow duration are presented for each station. A computed monthly 7-day, 10-year low flow is presented for 142 stations with flow patterns not significantly altered by controls or affected by other influences. (USGS)

FLOOD PROFILES IN THE CALAPOOYA CREEK BASIN, OREGON,
Geological Survey, Portland, OR. Water Resources Div.
J. Friday.
Available from the OFSS, USGS, Lakewood CO 80225; Paper copy $4.50, Microfiche $3.50. USGS Open-File Report 82-439, 1982. 30 p, 7 Sheet maps, 16 Fig, 3 Tab, 4 Ref.

Descriptors: *Floods, *Flood profiles, *Floodway, Surcharge, Computer model, *Oregon, Douglas County, Umpqua River, Calapooya Creek basin.

Water-surface profiles were computed for a 19.4-mile reach of Calapooya Creek in Douglas County, Oregon. The data will enable the county to evaluate flood hazards in the floodprone areas in the reach. Profiles for floods having recurrence intervals of 2, 10, 50, 100, and 500 years are shown in graphic and tabular form. A floodway, allowing encroachment of the 100-year floods, was designed with a maximum 1.0-foot surcharge limitation. A profile for a flood that occurred in November 1961 is also presented. All data were derived from a digital computer model developed for the study. (USGS)

WATER RESOURCES DATA, NORTH CAROLINA, WATER YEAR 1982,
Geological Survey, Raleigh, NC. Water Resources Div.
H. C. Gunter, C. L. Hill, and T. E. Dillard.
Available from the National Technical Information Service, Springfield, VA 22161 as PB83-243881, Price codes: A21 in paper copy, A01 in microfiche. USGS Water-Data Report NC-82-1, 1982. 481 p, 9 Fig, 1 Tab. Prepared in cooperation with the State of North Carolina and with other agencies.

Descriptors: *North Carolina, *Hydrologic data, *Surface water, *Groundwater, *Water quality, Flow rate, Gaging stations, Lakes, Reservoirs, Chemical analysis, Sediments, Water temperatures, Sampling sites, Water levels, Water analyses, *Data collections.

Water Resources data for the 1982 water year for North Carolina consist of records of stage, discharge, and water quality of streams; stage and contents of lakes and reservoirs; and ground-water levels. This report contains discharge records for 143 gaging stations and stage and contents for 25 lakes and reservoirs; water quality for 86 gaging stations and 3 miscellaneous sites; and water levels for 56 observation wells. Additional water data were collected at various sites not involved in the systematic data-collection program, and are published as miscellaneous measurements in this report. (USGS)

SMALL-STREAM FLOOD INVESTIGATIONS IN MINNESOTA, OCTOBER 1958 TO SEPTEMBER 1980,
Geological Survey, St. Paul, MN. Water Resources Div
K. T. Gunard, and C. J. Smith.
USGS Open-File Report 82-433, May 1982. 221 p, 9 Fig, 1 Tab, 8 Ref.

Descriptors: *Small watersheds, *Minnesota, *Peak discharge, *Floods, Streamflow, Gaging stations, Flow characteristics, Stage-discharge relations, Basin characteristics, Flood depth.

An investigation of flood flows from small drainage basins in Minnesota is being made to aid in the design of bridges, culverts and other highway drainage structures. Results of the investigation provide peak-flow data on streams generally with drainage areas less than 200 square miles, placing particular emphasis on those with drainage areas lees than 10 square miles. Basin parameters being investigated for their effect on floods are drainage area, length of main stream, slope of main channel, basin altitude, forest cover, and storage area. All of the 187 gaging stations included in the report are equipped with crest-stage gages. In addition, 4 stations are equipped to record stage and precipitation continuously. The relative magnitude of flood flows for different hydrologic regions is shown in graphs that relate maximum discharge to drainage area. Station records contain location, drainage area, records available, type of gage, on-site structure elevations, bankfull stage, and annual maximum stage and discharge data. These data, with annual peak data from continuous-record stations, form the basis for statewide flood-frequency studies. (USGS)

GENERALIZED CONFIGURATION OF THE TOP OF THE LIMESTONE UNIT OF THE LOWER PART OF THE SURFICIAL AQUIFER, DUVAL COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
R. M. Speechler.
USGS Open-File Report 82-336, 1982. 1 Sheet map, 2 Fig, 1 Tab, 6 Ref.

9

Descriptors: Geology, *Stratigraphy, *Aquifers, Surficial aquifer, Duval County, *Florida.

The top of the limestone unit ranges from about 25 feet above sea level in western Duval County to about 75 feet below sea level locally in the eastern part of the county. The limestone, which is part of the surficial aquifer, is the principal source of water to shallow wells in the county. The unit generally consists of a soft, friable, cavernous, sandy limestone, which ranges from about 5 to 40 feet in thickness. Along the coast and in the southern part of the county, the limestone becomes discontinuous. (USGS)

ANNUAL SNOWMELT AND RAINFALL PEAK-FLOW DATA ON SELECTED FOOTHILLS REGION STREAMS, SOUTH PLATTE RIVER ARKANSAS RIVER, AND COLORADO RIVER BASINS, COLORADO,
Geological Survey, Lakewood, CO. Water Resources Div.
J. G. Elliott, R. D. Jarrett, and J. L. Ebling.
Available from the OFSS, USGS, Lakewood, CO 80225, Price: $11.50 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-426, 1982. 86 p, 7 Fig, 1 Tab, 25 Ref.

Descriptors: *Flood hydrology, *Peak discharge, *Snowmelt hydrograph, *Rainfall hydrograph, Foothills region, Mixed population, Data collection, *Colorado, *South Platte River basin, Arkansas River basin, Colorado River basin.

Peak flows in the foothills region of Colorado are attributable to two meteorological sources--snowmelt and rainfall. As part of a study of the hydrology of foothills streams in Colorado, charts from streamflow gages on unregulated streams were examined to determined the source of peak-flow events. Snowmelt-runoff peaks were distinguished from rainfall-runoff peaks on the basis of daily and seasonal occurrence, hydrograph shape, and local weather conditions. Peak-flow data for snowmelt runoff and rainfall runoff are presented for 69 streamflow-gaging stations in the South Platte River, the Arkansas River, and the Colorado River basins. (USGS)
W84-01038

IDENTIFICATION AND CLASSIFICATION OF PERENNIAL STREAMS OF ARKANSAS,
Geological Survey, Little Rock, AR. Water Resources Div.
R. A. Hunrichs.
USGS Water-Resources Investigations Report 83-4063, 1983. 1 Sheet map, 7 Fig, 6 Ref.

Descriptors: *Perennial stream, *Low flow, Frequency analysis, *Arkansas, Recurrence intervals, *Classification.

Perennial streams are identified in a map and classified according to the relative magnitude of their 7-day, 10-year low flows. Perennial streams are identified for the entire State of Arkansas with the exception of the Mississippi Alluvial Plain. Also presented are the 7-day, 10-year low flow values at continuous-record and low-flow partial-record stations statewide. Perennial streams are defined in this report as having 7-day, 10-year low flows greater than zero. The perennial stream drainage was delineated using data from continuous-record and low-flow partial-record stations, and reconnaissance-site observations. The reconnaissance was conducted during the unusually dry summer of 1980. In analysis, the State was divided into hydrologic regions; they were used in conjunction with index stations to establish the recurrence intervals of flow observed, during the reconnaissance. When necessary, relations were developed by region to adjust observed flow to 10-year recurrence interval flows. (USGS)

R. E. Curtis, P. W. McKinley, and H. M. Colon-Ramos.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-114701, Price codes: A18 in paper copy, A01 in microfiche. USGS Water-Data Report PR-81-82-1, (March 1983). 414 p, 25 Fig, 3 Tab.

Descriptors: *Puerto Rico, *Surface water, *Water quality, *Groundwater, Aquifers, Chemical analysis, Gaging stations, *Hydrologic data, Sediments, Streamflow, Water analysis, Water levels, Lakes, Sampling sites, *Data collection.

Water-resources data for surface-water, quality-of-water, and ground-water records for 1981-82 water years for Puerto Rico consist of records of discharge, water quality of streams, and water levels of wells. This report contains discharge and water-quality records for 40 gaging stations, 109 water-quality stations, stage records for 3 lakes, and water levels for 61 observation wells. Also included are data for 17 crest-stage partial-record stations. (USGS)

: Adjudication, Compacts, Treaties, Stream Quality Accounting Network, ydrologic Benchmark Network fundologic data collection, *Federal pro-

gram activities in the collection and nydrologic data are funded in six catelished in order of priority. Over the to 1982, the funding available for the upported in each category has increased, but when viewed without the effect of inflation the purchasing power of the programs has generally decreased. Funding for adjudications, compacts, and treaties increased continuously from $588,600 in 1973 to $1,035,500 in 1981, and then decreased to $1,014,200 in 1982. However, when adjusted for inflation, based on a 1972 constant dollar, the constant dollars decreased from $555,800 in 1973 to $411,900 in 1982, which indicates that purchasing power was 26% less in 1982 than in 1973. Funding for the other five categories--the National Stream Quality Accounting Network, National Benchmark Network, Other Federal Agencies within the Department of the Interior, and General Federal Agencies Outside the Department of the Interior, and General Federal Hydrologic Interests--increased during the period, but the funding increase did not keep pace with inflation. During this 1973-82 period the U.S. Geological Survey has worked to make the Federal Data Collection and Analysis Program more cost effective by more efficient operational procedures and improved instrumentation, laboratory, and computation procedures. DEFINITIONS OF COMPONENTS OF THE MASTER WATER DATA INDEX MAINTAINED BY THE NATIONAL WATER DATA EXCHANGE,
Geological Survey, Reston, VA. Water Resources Div.
R. A. Perry, and O. O. Williams.
Available from the OFSS, USGS Lakewood, CO. 80225, Prices: $35.75 in paper copy, $4.00 in microfiche. USGS Open-File Report 82-327, 1982. 269 p, 2 Fig, 2 Tab, 34 Ref.

Descriptors: *Information systems, *Information retrieval, Data processing, Documentation, *Indexes, Surface waters, Groundwater, Water quality, *National Water Data Exchange, Dictionaries, *Water data sites, System 2000, *Data base management systems, Data dissemination.

The Master Water Data Index is a computerized data base developed and maintained by the National Water Data Exchange (NAWDEX). The Index contains information about water-data collection sites. This information includes: the identification of new sites for which water data are available, the locations of these sites, the type of site, the data-collection organization, the types of data available, the major water-data parameters for which data are available, the frequency at which these parameters are measured, the period of time for which data are available, and the medial in which the data are stored. This document, commonly referred to as the MWDI data dictionary, contains a definition and description of each component of the Master Water Data Index data base. (USGS)

ANNOTATED REPORT AND DATA INVENTORY FOR THE MISSISSIPPI RIVER QUALITY-ASSESSMENT, MINNEAPOLIS-ST. PAUL METROPOLITAN AREA,
Geological Survey, St. Paul, MN. Water Resources Div.
T. A. Winterstein.
Available from the OFSS, USGS, Lakewood, CO 80225, Price: $13.00 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-869, September 1982, 104 p.

Descriptors: *Bibliographies, *Abstracts, *Mississippi River, Water quality, Basic-data collections, Dissolved oxygen, Water chemistry, Water pollution effects, Aquatic life, Freshwater fish, Mussels, Aquatic plants, Aquatic algae, Nutrients, Biochemical-oxygen demand, *River-quality-assessment project, *Minnesota River, St. Croix River, Minneapolis-St. Paul metropolitan area.

This inventory of reports and data concerning the Mississippi and Minnesota Rivers in the Twin Cities metropolitan area was compiled from November 1981 through January 1982 for a planned river-quality assessment to be conducted cooperatively by the U.S. Geological Survey and the Metropolitan Waste Control Commission. There are 260 annotated citations: 176 citations of reports; 8 citations of computer models that have been used to model either or both rivers; and 76 citations of data in reports, in field notes, lab sheets, or handwritten tabulations, and in computer data bases. Citations of all the reports and data located that might conceivably be useful in understanding and interpreting the biological and chemical quality of the Mississippi and Minnesota Rivers in the past, present, or future were included. The accuracy of the citations was not verified and secondary sources, such as other annotated bibliographies, were used in the compilation of this inventory. (USGS)

LITERATURE ASSESSMENT OF THE CHARLOTTE HARBOR ESTUARINE SYSTEM AND SURROUNDING AREA, SOUTHWEST FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
Y. E. Stoker, and G. A. Karavitis.
USGS Open-File Report 83-127, 1983. 134 p, 1 Fig, 1289 Ref.

Descriptors: *Bibliographies, *Water quality, *Estuary, Freshwater inflow, *Marine resources, *Model studies, Fisheries, Groundwater, Surface water, Waste-load, Water use, *Charlotte Harbor, Peace River basin, Myakka River basin, Caloosahatchee River basin, Impacts, Biological assessment, Circulation, Radiochemicals, *Florida.

The Governor of Florida established the Charlotte Harbor Resource Planning and Management committee to recommend the course of action Florida should take in planning for potential growth in the rapidly growing area surrounding Charlotte Harbor. In May 1981, the U.S. Geological Survey began a planning study to determine detailed hydrologic study needs of the Charlotte Harbor area. A literature search of available data and reports pertaining to the Charlotte Harbor estuarine system and surrounding area resulted in almost 1,300 references. This report contains all references collected during this search. Some of the major reference topics are altered freshwater flow, water quality of the harbor and drainage systems, circulation and tides, coastal and marine resources, fisheries, geology and hydrology of the area, impact studies, water resources, flora and fauna of the area, and water supply. Sixty-eight key words or subject identifiers are used to the index report. (USGS)

REVISED DESCRIPTION OF INDEX OF FLORIDA WATER DATA COLLECTION ACTIVE STATIONS AND A USER'S GUIDE FOR STATION OR SITE INFORMATION RETRIEVAL COMPUTER PROGRAM FINDEX H578,
Geological Survey, Tallahassee, FL. Water Resources Div.
L. H. Geiger.
USGS Open-File Report 83-37, 1983. 76 p, 16 Fig, 3 Tab, 1 Ref.

Descriptors: *Computer program, *Hydrologic data, Data collection, *FINDEX, FNDXUP, FNDXST.

The report is an update of U.S. Geological Survey Open-File Report 77-703, which described a retrieval program for administrative index of active data-collection sites in Florida. Extensive changes to the Findex system have been made since 1977, making the previous report obsolete. A description of the data base and computer programs that are available in the Findex system are documented in this report. This system serves a vital need in the administration of the many and diverse water-data collection activities. District offices with extensive data-collection activities will benefit from the documentation of the system. Largely descriptive, the report tells how a file of computer card images has been established which contains entries for all sites in Florida at which there is currently a water-data collection activity. Entries include information such as identification number, station name, location, type of site, county, frequency of data collection, funding, and other pertinent details. The computer program FINDEX selectively retrieves entries and lists them in a format suitable for publication. The index is updated routinely. (USGS)

SELECTED WATER RESOURCES ABSTRACTS

The Library of the
APR 11 1984
University of Illinois
at Urbana-Champaign

VOLUME 17, NUMBER 4
APRIL 1984

051 -- W84-01400
I: SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 4
APRIL 1984

W84-01051 -- W84-01400

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

AND NITRATE-NITROGEN LOSSES A SMALL, UPLAND, COASTAL PLAIN SHED,
ural Research Service, Tifton, GA. South-ershed Research Center.
bbard, and J. M. Sheridan.
f Environmental Quality, Vol. 12, No. 2, 5, April-June, 1983. 4 Fig, 2 Tab, 13 Ref.

ors: *Surface runoff, *Storm seepage, *Ni-easonal variation, Mathematical studies, Water pollution sources, Prediction, atersheds, Coastal plain.

Surface runoff (SRO) and shallow-subsurface flow (SSF) from a small, upland, Coastal Plain watershed underlain by plinthite were monitored for a 10-yr period. Samples collected during surface runoff and subsurface-flow events were analyzed for NO3-N. The major water runoff loss from the system was found to be subsurface flow, accounting for 79% of total runoff loss, which occurred primarily from December through May. Nitrate-N concentrations in surface runoff and subsurface flow were relatively uniform over the period, averaging 0.47 and 8.75 mg/L, respectively. The combination of high volume of subsurface flow and its relatively high NO3-N content, resulted in 99% of total NO3-N loss via subsurface flow. Predictive equations for monthly surface and subsurface water runoff losses from this watershed were developed using multiple linear regression. The equations contain seasonal and climatic parameters, including pan evaporation. Tests of the equations with observed results gave significant ($P < \text{or} = 0.01$) correlation coefficients, r, of 0.82 and 0.85 for surface runoff and subsurface flow, respectively. Mean surface and subsurface NO3-N concentrations were multiplied by predicted monthly flows to compute predicted monthy NO3-N losses. Comparison of predicted and actual monthly NO3-N losses gave significant ($P < \text{or} = 0.01$) correlation coefficients, r, of 0.59 and 0.86 for surface and subsurface flows, respectively. The good fit of predicted and observed results can be partially attributed to the seasonal and climatic data base collected over a relatively long period of 10 yr. (Author's abstract)

HYDROLOGY OF THE JORDAN TRIBUTARIES (ISRAEL): HYDROGRAPHIC AND ISOTOPIC INVESTIGATION,
Weizmann Inst. of Science, Rehovoth (Israel). Dept. of Isotope Research.
B. Simpson, and I. Carmi.
Journal of Hydrology, Vol. 62, No. 1-4, p 235-242, April, 1983. 9 Fig, 1 Tab, 24 Ref.

Descriptors: *Geohydrology, *Isotope studies, *Groundwater movement, *Interflow, Tributaries, Jordan River, Oxygen isotopes, Tritium, Hydrograph analysis, Groundwater reservoirs, Rainfall, Springs, Catchment areas, Flow discharge.

Nahal Dan, Nahal Snir and Nahal Hermon are the three principal tributaries of the Jordan River. All three are spring-fed and appear to derive their discharges from the same regional groundwater aquifer. The behavior of this aquifer is examined by hydrograph separation and multivariate time-series analysis of discharge and rainfall records, and by investigation of O18 and tritium records. Hydrograph separation gives base-flow recession constants of 11-20 months and in addition Nahal Snir and Nahal Hermon show an interflow recession of about 1 month. The dual reservoir system for these two tributaries is confirmed by time-series analysis. O18 data distinguish the different catchments for the springs and support the idea that interflow occurs in the near-surface part of the regional groundwater reservoir. Tritium data illustrate the inhomogeneity of the karstic reservoir. Assuming well-mixed conditions, the difference in behavior between tritium records for rainfall and the tributaries is used to estimate the age distribution of water in the reservoir. At any time 50% of the storage is less than 1 yr old and 90% is less than 3 yr old. (Author's abstract)

DESIGN AND CONSTRUCTION OF THE THAMES BARRIER COFFERDAMS,
J. R. Grice, and E. A. Hepplewhite.
Proceedings of the Institution of Civil Engineers, Vol. 74, p 191-224, May, 1983. 1 Tab, 23 Fig, 4 Ref.

Descriptors: *Cofferdams, *Flood control, Thames Barrier, England, Design criteria, Construction, Excavation, Underwater, Piers, Abutments, River beds.

Heavy cofferdams were required to facilitate construction in the dry of the piers and abutments of the Thames Barrier at Woolwich (England) which is a flood defense barrier intended to protect London from flooding. The civil works were carried out in two main phases and different basic cofferdam designs were adopted for the two phases. In addition to the effects of differential soil and water levels on either side of the cofferdam walls, the design took into account surcharge of the river bed by sand-filled fairing cells located close to the cofferdam ends, and possible lateral loading transferred through the soil from adjacent fender structures. The design allowed for the excavation and the placing of the concrete base plug being carried out underwater, with unbalanced waterloads on the walls prior to dewatering being limited by the use of sluices through the sheet piles near low water level. To minimize interference with working space, no vertical bracing was provided. The larger cofferdams, 29 m deep, had four strutting frames in the phase 1 design, but only one in phase 2. Eleven deep cofferdams were constructed between 1974 and 1980 to enable nine piers and two abutments to be built across the river. (Moore-IVI)

WATER BUDGETS FOR SMALL DIKED MARSHES,
Utah State Univ., Logan. Dept. of Fisheries and Wildlife.
J. A. Kadlec.
Water Resources Bulletin, Vol. 19, No. 2, p 223-229, April, 1983. 1 Fig, 4 Tab, 15 Ref.

Descriptors: *Marshes, *Hydrologic budget, Dikes, Cycling nutrients, Precipitation rate, Hydrologic cycle, Evapotranspiration, Seepage, Water storage, Hydraulic gradient, Permeability coefficient, Manitoba.

This paper reports an analysis of the water budgets of 10 small (5-6 ha) diked areas (cells) within the Delta Marsh in Southcentral Manitoba, Canada. The important terms in the water budget equation in this study were precipitation (P), water pumped in (SWI), evapotranspiration (ET), seepage in (GWI) and out (GWO), and change in storage (delta S). P, SWI and S were measured directly, and the sum of ET and GWO determined by difference. Estimating ET as 0.7 pan evaporation gave a seepage loss of 2.9 mm/day from the most intensively studied cell. Other methods of estimating ET produced estimates of GWO ranging from 2.4 to 3.8 mm/day. Water budgets for less intensively studied cells indicated seepage loss increased as perimeter available for seepage increased, but not proportionately. Efforts to measure seepage directly or estimate it from measured hydraulic gradients and hydraulic conductivity produced estimates much lower than the estimates from the water budget equation. Hydraulic conductivities were very heterogeneous, reflecting the sorting of water deposited sediments. Comparison of the hydraulic conductivities with seepage estimates from the water budget strongly suggests water movement downward as well as laterally from these diked areas. (Author's abstract)

EVALUATIONS OF WATER BALANCE MODELS ON A MIXED CONIFER WATERSHED,
Rocky Mountain Forest and Range Experiment Station, Flagstaff, AZ.
M. B. Baker, Jr., and J. J. Rogers.
Water Resources Research, Vol. 19, No. 2, p 486-492, April, 1983. 1 Fig, 9 Tab, 15 Ref.

Descriptors: *Hydrologic budget, *Mathematical models, *Evapotranspiration, *Streamflow, Forest watersheds, Runoff volume, Zero discharge, Snowmelt, Intermittent streams.

ARZMLT, BURP and ECOWAT, three water balance and yield models of differing degrees of complexity, were evaluated using data from a mixed conifer watershed in east-central Arizona. Statistical tests on simulated monthly flow volumes are provided with a comparison of 5-year mean annual estimates of evapotranspiration and streamflow. ARZMLT accounts for 87% of the variation

in monthly flow but produces the most bias in simulated monthly runoff volume. BURP accounts for 78% of the monthly streamflow variation and produces the least bias in monthly streamflow volume. The greatest problem with BURP is its inability to simulate zero flow events. Statistics for ECOWAT generally lie between those of the other two models. In an area where intermittent streamflow conditions exist and the majority of flow is from snowmelt, ECOWAT can be used without acquiring much additional error. Results from ARZMLT indicate that some structural changes in the model are needed to simulate the prevalent runoff conditions that exist in the southwest. (Moore-IVI)

MODELING THE EFFECTS OF A TIME-DEPENDENT WETTED PERIMETER ON INFILTRATION FROM EPHEMERAL CHANNELS,
Stanford Univ., CA. Dept. of Civil Engineering.
D. L. Freyberg.
Water Resources Research, Vol. 19, No. 2, p 559-566, April, 1983. 12 Fig, 12 Ref. ENG 76-01271.

Descriptors: *Infiltration, *Ephemeral streams, Channel geometry, Mathematical models, Soil water, Hydrographs, Wetted perimeter, Soil water flow, Vertical infiltration.

The effects of a time-dependent wetted perimeter on infiltration from ephemeral stream channel cross sections are explored using a conceptually simple mathematical model. The model is based on the assumptions of vertical soil moisture flow and the validity of the Green-Ampt model for vertical infiltration. By using a simple channel geometry, an analytic solution is found for the case in which the gravitational component of soil moisture flow may be neglected. An efficient, accurate numerical technique provides approximate solutions in the general case. Application of the model demonstrates that cross-sectional infiltration, that is, infiltration per unit length of channel, is a complex function of soil properties, channel geometry, and hydrograph shape. For the channel geometry considered, the direct effects of variable water pressure at the ground surface are overshadowed by the effects of variation in the wetted perimeter, with the result that the temporal variation in infiltration rate is quite unlike that which would be predicted assuming ponded infiltration alone. (Author's abstract)

COUPLED SURFACE WATER AND GROUNDWATER CATCHMENT MODEL,
University Coll., Cardiff (Wales). Dept. of Civil and Structural Engineering.
J. C. Miles, and K. R. Rushton.
Journal of Hydrology, Vol. 62, No. 1-4, p 159-177, April, 1983. 10 Fig, 1 Tab, 19 Ref.

Descriptors: *River basins, *Catchment areas, *Groundwater movement, *Surface flow, Hydrologic models, Mathematical models, Aquifers, Rainfall, Evapotranspiration, Geohydrology.

For river catchments in which there is significant interconnection between aquifers and the river, a thorough understanding of the way in which water is exchanged between the river and the underlying strata is important for resources planning. The formation of a model to represent surface and subsurface flows of water for a catchment in central England is described. A finite-difference model is used to represent groundwater flows in an aquifer with surface water flows being represented by flow balance techniques. Three hydrologically significant land types have been identified in the catchment: aquifer covered by permeable deposits; low-permeability strata covered by permeable deposits; and areas covered by impermeable drift. The model contains three components which correspond to these. The mode has been designed to be used as a tool for determining the long-term environmental effect of abstraction from the catchment. River flows are calculated for over 120 locations within the catchment. The results show that it is possible to formulate a comprehensive model, of a complete catchment, based upon measurable, physical parameters with the inflow of water being calculated solely from rainfall and evapotranspiration estimates. (Moore-IVI)

2B. Precipitation

DAILY PRECIPITATION OCCURRENCES MODELLING WITH MARKOV CHAIN OF SEASONAL ORDER,
National Technical Univ., Athens (Greece). Dept. of Civil Engineering.
M. Mimikou.
Hydrological Sciences Journal, Vol. 28, No. 2, p 221-232, June, 1983. 2 Fig, 3 Tab, 10 Ref.

Descriptors: *Precipitation, *Seasonal distribution, *Model studies, Markov process, Mathematical studies, Storm duration, Altitude.

The seasonality of the Markov chain order for properly modelling daily precipitation occurrences for precipitation stations in Greece is studied. The average seasonal storm duration, being the average seasonal ratio of the number of wet days to the number of storm events and influenced by the meteorology and geography of the station, is proposed as a criterion for determining the proper seasonal Markov order. For the records studied, and on a monthly basis, the latter, minimizing the chain's modelling error, is the closest positive integer to the average storm duration in days reduced by one. Orders greater than 1 are prevalent in wet periods, whereas in dry periods orders of 1 or 0 predominate. The appearance of the period with orders higher than 1 is delayed and its duration decreases towards the east and with decreasing altitude. The monthly sums of wet days are modelled better by a second order autoregressive model than by aggregating daily precipitation occurrences generated from a Markov chain. (Author's abstract)

SOCIATIONS BETWEEN ANOMALIES OF MPERATURE AND PRECIPITATION IN E UNITED STATES AND WESTERN RTHERN HEMISPHERE 700 MB HEIGHT OFILES,
tional Climatic Center, Asheville, NC.
F. Diaz, and J. Namias.
rnal of Climate and Applied Meteorology, Vol. No. 3, p 352-363, March, 1983. 7 Fig, 3 Tab, 25 f. NOAA/NA81-AA-D-00054, NSF-ATM81-15.

scriptors: *Precipitation, *Climatology, *Sea-al distribution, Air temperature, Latitudinal dies, Temperate zone, Midtropospheric height, ather patterns.

e relationship between anomalous seasonal sur-e temperature and precipitation in the contigu-ous United States and concomitant fluctuations of western Northern Hemisphere 700 mb height as a function of latitude are examined. Findings are consistent with other studies dealing with the spatial patterns of midtropospheric teleconnections and their surface manifestations. A strong inverse relationship between temperature in the eastern United States and heights in the western Northern Hemisphere polar regions is present during winter and spring, especially in winter. In summer, the association is positive and is most evident in the southern tier of states. Fewer significant correlations are found between seasonal precipitation and midtropospheric height, with the strongest ones occurring in winter and summer. No correlation coefficient was statistically significant for the autumn season. Where significant, the regional precipitation variance of the other three seasons accounted for by the 700 mb height field varies from 11-44% in winter to 11-30% for spring and summer. Spatial coherence of the correlation pattern is appreciable but is not as strong as for temperature. In winter, during the period 1948-81, the frequency of below-average 700 mb heights has increased in the temperate latitudes of the western Northern Hemisphere. At the same time, a general increase in above normal polar latitude heights has taken place. This in turn has been associated with lower winter temperatures in the eastern United States. (Moore-IVI)

ON THE ANALYSIS OF EXTREME RAINFALLS,
Meteorological Service, Wellington (New Zealand).
K. J. A. Revfeim.
Journal of Hydrology, Vol. 62, No. 1-4, p 107-117, April, 1983. 2 Tab, 8 Ref.

Descriptors: *Rainfall, *Statistical models, *Recurrence time, Rainfall distribution, Return period, Temporal distribution, Rainfall extremes, Model studies, Mathematical models.

Two standard analyses of rainfall records are to obtain the expected maximum amount (depth) within a given time interval or expected recurrence time (return period) of a given rainfall amount. The methods in common practice assume little or nothing about an underlying time-dependent rainfall process. A simple recurrence model which represents the rainfall process in an intuitively realistic manner is developed in this paper. The statistical properties of the model provide small sample estimates of maximum amounts and recurrence times. Anomalies in rainfall analysis based on asymptotic theory do not occur in the recurrence model. (Author's abstract)

ERRORS IN THE THIESSEN TECHNIQUE FOR ESTIMATING AREAL RAIN AMOUNTS USING WEATHER RADAR DATA,
McGill Univ., Montreal (Quebec). Stormy Weather Research Group.
C. Damant, G. L. Austin, A. Bellon, and R. S. Broughton.
Journal of Hydrology, Vol. 62, No. 1-4, p 81-94, April, 1983. 4 Fig, 6 Tab, 21 Ref.

Descriptors: *Rain gages, *Radar, *Rainfall distribution, Thiessen polygon method, Weather data collections, Storms, Watersheds, Yamaska River watershed, Convective precipitation.

High-resolution radar data were used to estimate rainfall accumulation patterns for thirteen summer storms over the Yamaska River watershed. The results were compared with those obtained using the Thiessen polygon method. For any of the storms the error varied from $<8\%$ to $>100\%$ for each size subcatchment. The size of the error depended on the rainfall gradients produced by each storm and not greatly either on the area size or on the number of polygons associated with the area. The average error for all thirteen storms together over each subcatchment size varied between 15% and 84%, whereas the error over the entire watershed for each storm varied between 3% and 69%. The average error for all storms over the whole basin was 19%. It is concluded that for showery rain at least, the errors associated with using gage data are of significant magnitude and that users of streamflow models should be careful in the use of these data for convective showers. This paper also provides a review of some of the problems of estimating the spatial distribution of rain from both radar and raingage data. (McKeon-IVI)

SPATIAL-TEMPORAL MODEL OF STORM RAINFALL,
Leeds Univ. (England). Dept. of Statistics.
R. J. Marshall.
Journal of Hydrology, Vol. 62, No. 1-4, p 53-62, April, 1983. 5 Fig, 5 Ref.

Descriptors: *Rainstorms, *Statistical models, Rainfall distribution, Simulation analysis, Weather patterns, Model studies, Storms, Spatial distribution, Temporal distribution.

A multiple time series model is proposed to describe the spatial and temporal distribution of small-scale rainfall patterns. The model has seven parameters and is characterized by a multiple autoregressive scheme that has the property of its correlation structure being factorized into space-time components. Such a factorization explains the observed correlation structure of 2-min. rainfall of storms recorded by the Cardington and Winchcombe, England networks. The model can also be adapted to simulate within storm sequences or to generate moving storm sequences. (McKeon-IVI)

WEST AFRICAN WATER VAPOR VARIATIONS BETWEEN RECENT CONTRASTING SUBSAHARAN RAINY SEASONS,
Illinois State Water Survey, Champaign. Climatology and Meteorology Section.
P. J. Lamb.
Tellus, Vol. 35A, No. 3, p 198-212, May, 1983. 3 Fig, 5 Tab, 23 Ref.

Descriptors: *Water vapor, *Monsoons, West Africa, Seasonal variation, Drought, Rainfall, Rainy season.

Investigation is made of the interannual and intraseasonal variability of the southwest monsoon layer's thickness and moisture content over West Africa, and its water vapor supply to this region from the tropical Atlantic, for the Subsaharan (10 degrees - 20 degrees N) rainy season of July-September. Results for the very deficient 1968, 1971, and 1972 Subsaharan rainy seasons, whose departures from the 1941-74 mean ranged between -0.78 sigma and -1.39 sigma, are compared with those for the near-average rainy seaons of 1967, 1969, and 1975 (-0.27 sigma to +0.06 sigma). The observational base consists of monthly mean rawinsonde data from West African stations and seasonal estimates of the tropical Atlantic near surface specific humidity field. Subsaharan drought does not appear to be associated with the northward supply of unusually dry surface air to West Africa from the tropical Atlantic. Over West Africa, the magnitude of the vertically integrated monsoon layer advective water vapor flux tends to be proportional to the layer thickness. The extremely poor 1972 Subsaharan rain season (-1.39 sigma) coincided with particularly shallow southwesterly flow across the Gulf of Guinea coast (about 5 degrees N); thicker monsoon layers are found characteristic of the less severe 1968 (-0.78 sigma) and 1971 (-0.88 sigma) droughts. However, the monsoon layer depth here during the non-drought study years does not always exceed that for drought months. The direction of the low level water vapor flux above Dakar, a sensitive Subsaharan location (about 15 degrees N) on the West African coast, shows a stronger tendency to be from north of west during unproductive Subsaharan rainy season (-0.78 sigma to -1.39 sigma) than in near-average ones (-0.27 sigma to +0.06 sigma). This suggest the southwest monsoon does not extend as far north along the West African coast during Subsaharan droughts as in more abundant rainy seasons. In contrast to the foregoing Gulf of Guinea results, the monsoon layer over the interior

of the Subsaharan zone at about 13 degrees N exhibits minimal variability for the drought study years. The better developed nondrought southwesterly flows here tended to be thicker than those characteristic of most drought months. (Author's abstract)

SATELLITE OBSERVATIONS OF THE SOUTHERN HEMISPHERE MONSOON DURING WINTER MONEX,
Australian Numerical Meteorology Research Centre, Melbourne.
J. L. McBride.
Tellus, Vol. 35A, No. 3, p 189-197, May, 1983. 4 Fig, 1 Tab, 30 Ref.

Descriptors: *Monsoons, *Satellite technology, Infrared imagery, Convection, Tropical cyclones, Southern hemisphere.

Time-longitude strips of infrared GMS satellite imagery have been used to study the southern hemisphere summer monsoon during Winter MONEX (International Monsoon Experiment). This representation reveals a sudden monsoon onset in late December characterized by a transition to spatially organized convection. Active and break regions of the monsoon show a strong coherence in time but are very longitudinally dependent. The latitudinal dependence, on the other hand, is quite weak. The dominant spatial scale over which changes in convection take place is of order 35 degrees longitude by 15 degrees latitude. These synoptic scale convective regions can move in either the eastward or west direction. Typical phase speeds of movement range between 3 and 8 degrees longitude per day. Tropical cyclones in the region are revealed to be embedded in the large-scale monsoon circulation. (Author's abstract)

PATTERNS OF INDIA MONSOON RAINFALL ANOMALIES,
Wisconsin Univ.-Madison. Dept. of Meteorology.
S. Hastenrath, and A. Rosen.
Tellus, Vol. 35A, No. 4, p 324-331, August, 1983. 5 Fig, 1 Tab, 26 Ref. ATM76-09784, ATM79-11131.

Descriptors: *Rainfall distribution, *Monsoons, India, Tropical cyclones, Pattern stratification, Spatial distribution, Temporal distribution.

Pattern characteristics of annual rainfall anomalies over India during 1900-72 are studied from precipitation records of 31 regional subdivisions and series of annual cyclone frequency and number of break monsoon days. Methods include spatial correlation, pattern stratification, and principal component and spectral analyses. Pattern stratification with respect to an all-India rainfall index yields largest concordant departures in the Central and Western portions of the country. Pattern stratification with respect to the largest annual frequency of cyclonic storms in the Bay of Bengal and Arabian Sea show large positive rainfall departures over Eastern, Southeastern and Western India, and negative departures in the North and a limited area of the Southwest; for the collective of years with smallest storm frequency a partly inverse rainfall anomaly pattern is obtained. Pattern stratification with respect to the years of most numerous break monsoon days yields deficient rainfall in a large, broadly zonally oriented band across Central India, and positive departures in most other parts of the country. Stratification with respect to the least numerous break monsoon days yields a broadly inverse pattern. The first eight principal component patterns account for 74% of the total variance. The first component resembles the pattern obtained by stratification with respect to the all-India rainfall index, the two time series being highly positively correlated. The third component is approximately inverse to the pattern constructed from stratification with respect to the most numerous break monsoon days, the two time series being negatively correlated. The seventh component is similar to the pattern derived from stratification with respect to the largest frequency of cyclonic storms: this is consistent with the positive correlation between the two time series. No physical significance is apparent for the other principal components. The combination of the various analysis techniques thus serves to identify spatial and temporal pattern characteristics of possible physical significance. (Author's abstract)

A SIMPLIFIED SEMIEMPIRICAL APPROACH TO PROBABILITIES OF EXTREME HYDROLOGIC DROUGHTS,
Auburn Univ., AL. Dept. of Civil Engineering.
O. Guven.
Water Resources Research, Vol. 19, No. 2, p 441-453, April, 1983. 13 Fig, 3 Tab, 33 Ref.

Descriptors: *Drought, *Streamflow, Probability distribution, Statistical models, Drought severity, Drought duration, Markov process.

On the basis of an available theory approximately valid for stationary first-order two-state Markovian processes and an assumption that the distribution of drought severity is approximately two-parameter gamma, a semiempirical method is proposed for the estimation of the probabilities of extreme drought durations and severities which may occur in the annual flow sequence of a stream during a period of finite length. The method is applied to the annual flows of eight streams in various parts of the world, and the semiempirical probability distributions obtained using this method are compared with experimental distributions obtained using synthetic streamflows generated with a lag one Markov model as well as a long-memory broken line model. The comparisons suggest that considerable insight into the extreme drought probabilities can be gained by the use of the simple semiempirical method introduced here. (Author's abstract)

AN INVESTIGATION OF THE CELLULAR STRUCTURE OF STORMS USING CORRELATION TECHNIQUES,
Lancaster Univ., Bailrigg (England). Dept. of Environmental Sciences.
S. R. Shaw.
Journal of Hydrology, Vol. 62, No. 1-4, p 63-79, April, 1983. 7 Fig, 4 Tab, 19 Ref.

Descriptors: *Statistical methods, *Rainfall distribution, Rainstorms, Storms, Wind, Statistical analysis, Storm cells.

A statistical technique called 'full correlation analysis' has been applied to short-time interval rain data for 8 intense storms recorded at 2 raingauge networks set up by the British Meteorological Office. The technique has been used to investigate the cellular structure of the storms. Certain important storm parameters were estimated including the velocity and direction of movement of the surface rainfall pattern, its mean spatial scale and its lifetime. The results of the analysis suggested a typical cell size of the order of 3 x 1.5 km. The velocities and directions of movement of the surface rainfall patterns agreed well with the 700-mbar wind velocities recorded at the time of the storm. The average lifetime of the storm cells varied from 4 to 6 min. at one network to considerably longer periods at the second network. It appears that the technique of full correlation analysis is particularly suited for application to rain data of the type provided by long storms for which the corresponding meteorological observations were consistent with the existence of cumuliform convective cells embedded in the large-scale cloud mass and for which the centers of these storm cells pass over the recording network. sible cyclic behavior of polar ice sheets is stud-with a numerical ice-flow model. The model ludes a calculation of bedrock adjustment and perature field in the ice sheet. Basal water is ced and affects ice-mass discharge. Relaxation illations occur only for low ice-accumulation es (less than 5 cm ice depth per year). For larger accumulation rates, 2 steady-state regimes exist, pending on temperature: an ice sheet frozen to bottom, and an ice sheet subject to basal melt-everywhere. The volume of the latter is con-erably smaller (about 65% of that of the 'cold et'). In general, the mean basal ice temperature reases with increasing ice accumulation rate. is is due to the advection term in the heat ation (which has been ignored in earlier studies ice-sheet surging). ONE-DIMENSIONAL STOCHASTIC MODEL OF ICE MOTION IN WESTERN NORTON SOUND, ALASKA, U.S.A.,
Alaska Univ., Fairbanks. Geophysical Inst.
W. J. Stringer.
Arctic and Alpine Research, Vol. 15, No. 2, p 213-221, May, 1983. 5 Fig, 1 Tab, 10 Ref.

Descriptors: *Floating ice, *Ice drift, *Statistical models, Model studies, Sounds, Pack ice, Oil spills, Fate of pollutants, Ice budget, Alaska.

Analysis of short-term ice-floe displacement fields in western Norton Sound, Alaska, yields a statistical model for long-term ice-floe drift. The short-term ice motions are found to be normally distributed with an average velocity of 3.6 km/d westward, i.e., toward the entrance of the sound, and with a standard deviation of around 6 km/d. These short-term data are used to develop a one-dimensional stochastic model to describe long-term ice drifts along the axis of the sound. The statistically projected, long-term drifts are compared with observed long-term drifts and found compatible. These results indicate that although pack ice within Norton Sound is generally moving toward its entrance, a high degree of variability also exists such that even after a period as long as twenty days, a 70% probability remains of a net motion into the sound. These data are used to estimate the annual ice budget for Norton Sound and the fractional contribution of Norton Sound ice to the Bering Sea ice budget. In addition, the results are used to characterize the possible fate of a petroleum spill associated with pack ice in Western Norton Sound. (Author's abstract)

ESTIMATING UNIT HYDROGRAPH PEAK RATE FACTORS,
Maryland Univ., College Park. Dept. of Civil Engineering.
R. H. McCuen, and T. R. Bondelid.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 2, p 238-250, June, 1983. 3 Fig, 2 Tab, 11 Ref.

Descriptors: *Hydrologic models, *Peak rate factor, Watersheds, Hydrographs, Runoff volume, Drainage area, Coastal areas, Mathematical models.

The Soil Conservation Service (SCS) dimensionless unit hydrograph model TR-20 is widely used for hydrologic design. The model uses a dimensionless unit hydrograph, with the drainage area, the depth of the runoff volume, the time-to-peak, and the SCS peak rate factor required to dimensionalize the unit hydrograph. A standard value of 484 for the peak rate factor is commonly used. While vague guidelines have been provided for modifying the value of the parameter, almost all designs are made using a value of 484. A method is presented that provides a systematic means of obtaining a value of the peak rate factor that is unique to a watershed. The method only requires a runoff curve number map, which should be developed to use the TR-20 model anyway. Application of the method to six watersheds, including three coastal basins, indicated that the method increases the accuracy of prediction; the peak rate factors computed using the procedure outlined compared very favorably with the values obtained by optimizing on measured rainfull hyetographs and runoff hydrographs. The results indicate that the value of 484 is too large for coastal watersheds on the Delmarva peninsula. (Author's abstract)

ON THE MATHEMATICS OF STORAGE ROUTING,
Vanderbilt Univ., Nashville, TN. Dept. of Civil and Environmental Engineering.
C.-N. Chang, E. Da Motta Singer, and A. D. Koussis.
Journal of Hydrology, Vol. 61, No. 4, p 357-370, March, 1983. 3 Tab, 14 Ref.

Descriptors: *Routing, *Storage, Mathematical models, Simulation, Flood routing, Muskingum scheme, Hydrologic models, Storage routing.

Some mathematical aspects of storage routing are investigated analytically and through numerical simulation. The minimum size of the time interval required to eliminate computed values at the beginning of the outflow hydrograph falling below the initial steady flow rate is given for two routing schemes. The stability behavior of a refined Muskingum scheme is explored; it is found that values of the weighting coefficient up to 1.0 may be used with appropriately specified time intervals. The concept of 'relative' storage is analyzed and it is shown that it is unnecessary when the correct initial condition of the storage is considered. The classical best straight-line fit procedure between storage and weighted discharge is investigated. In an example case, it is demonstrated that this method of system identification is not reliable. The possibility of using discharge-dependent parameters is discussed. (Author's abstract)

MECHANISM OF RUNOFF GENERATION FROM AN ALPINE GLACIER DURING A STORM TRACED BY OXYGEN O18/O16,
Vrije Univ., Amsterdam (Netherlands). Inst. of Earth Sciences.
A. A. Van de Griend, and J. A. Arwert.
Journal of Hydrology, Vol. 62, No. 1-4, p 263-278, April, 1983. 5 Fig, 2 Tab, 14 Ref.

Descriptors: *Glaciers, *Storm runoff, Snowmelt, Rainfall-runoff relationships, Oxygen isotopes, Snow accumulation, Glaciohydrology, Glacial runoff, Isotope studies.

As a result of progressive fractionation and seasonal effects in snow accumulation on a glacier, O18/O16 ratios of glacier meltwater differ significantly from those of summer precipitation. O18/O16 ratios of precipitation and runoff have been used to separate pluvial and glacial runoff components from an alpine glacier during one single storm. It was found, especially during the rising limb of the hydrograph, that the bulk of runoff consisted of pre-storm meltwater, stored in the glacier body. On the basis of the results a better insight could be gained into the storage push-through process in the glacier body, active during the storm. This leads to a distinction between recharge and discharge zones on the glacier, the discharge zone being the main source area for quick response on rainfall. Thus, the mechanism of runoff generation of the alpine glacier studied is comparable with that found in normal headwater catchments. (Author's abstract)

CHEMICAL COMPOSITION OF RAINWATER AND FLOODWATERS IN THE NEGEV DESERT, ISRAEL,
Ben-Gurion Univ. of the Negev, Sde Boker (Israel). Jacob Blaustein Inst. for Desert Research.
R. Nativ, A. Issar, and J. Rutledge.
Journal of Hydrology, Vol. 62, No. 1-4, p 201-223, April, 1983. 9 Fig, 6 Tab, 23 Ref.

Descriptors: *Floodwater, *Rainwater, *Water chemistry, *Salts, Deserts, Calcium, Magnesium, Sodium, Potassium, Carbonates, Chloride, Sulfates, Ions, Catchment areas, Lithology, Israel.

Rain and floodwater were sampled by self-sealing samplers scattered over the area of two drainage basins in the Negev Desert of Israel. The sampling was carried out during the winters of 1978-1981. Water was analyzed for the following ions: Ca(2+), Mg(2+), Na(+), K(+), HCO3(-), Cl(-) and SO4(2-). The chemical type of the rain and floodwater as well as the total quantities of salts

precipitated and drained out from the basins were investigated. The chemical characteristics of the rainwater falling in the Negev resemble those of rainwater in northern Israel, but the absolute quantities of ions are smaller. The total quantities of salts introduced into the basin were found to be larger than the quantities of salts drained out by the floods. The chemical composition of the floodwater was found to be governed by the lithology of the drainage basin and not by the initial chemical characteristics of the rain from which it was derived. UNIT-STEP FUNCTION RESPONSE FOR SEVERAL HYDROLOGICAL CONCEPTUAL MODELS,
Academia Sinica, Beijing (China). Inst. of Geography.
G.-T. Wang, and K. Wu.
Journal of Hydrology, Vol. 62, No. 1-4, p 119-128, April, 1983. 4 Ref.

Descriptors: *Rainfall-runoff relationships, *Mathematical models, Unit hydrographs, Laplace transform, Model studies.

To solve a rainfall runoff problem through the use of a conceptual model usually involves determining the instantaneous unit hydrograph (IUH) from rainfall and runoff records. In use it is necessary to convert the IUH into a unit hydrograph of finite duration D, DUH. For this the S-curve may be used. In this paper the rainfall data in 'blocks' of finite duration is represented by using the unit-step function. The output is obtained as the inverse Laplace transform of the product of the Laplace transform of the input so defined and the transfer function of the system. In this way output can be obtained corresponding to different conceptual models of the unit hydrograph. (Author's abstract)

ANNUAL FLOODS IN SOUTHWESTERN BRITISH COLUMBIA, CANADA,
McMaster Univ., Hamilton (Ontario). Dept. of Geography.
P. Waylen, and M.-K. Woo.
Journal of Hydrology, Vol. 62, No. 1-4, p 95-105, April, 1983. 4 Fig, 1 Tab, 7 Ref.

Descriptors: *Annual floods, *Gumbel distribution, *Snowmelt, *Rainfall, British Columbia, Seasonal distribution, Hydrology, Mathematical models.

In southwestern British Columbia there exists a transition from rain-generated floods in the west to snowmelt floods in the east. When a single process dominates, the Gumbel distribution provides an adequate fit to observed flood exceedance probabilities. The two processes produce distinct timing and magnitude characterizations in the resultant floods. The area of transition between these two sets of conditions displays varying mixtures of both characteristics which can best be fitted by a compounded Gumbel distribution. It is proposed that this technique is generally applicable wherever annual flood series are generated by more than one hydrological process. (Author's abstract)

COMPUTER MODELLING OF SNOWMELT FLOOD RUNOFF IN NORTH-EAST ENGLAND,
D. R. Archer.
Proceedings of the Institution of Civil Engineers, Vol. 75, p 155-173, June, 1983. 5 Fig, 3 Tab, 29 Ref.

Descriptors: *Snowmelt, *Flood forecasting, *Runoff rates, Computer models, Simulation, Flood hydrographs, England.

Components of snow models, as related to British conditions, are discussed. A computer simulation model is described in which the snowmelt phase is linked with alternative systems of lumped or distributed catchment routing. The catchment phase of the model is calibrated using winter rainfall events on three upland catchments in north-east England. Then, with fixed catchment routing parameters for a particular catchment, snow phase parameters are optimized. Observed snowmelt runoff hydrographs are satisfactorily reproduced by model simulation, in most events. Results confirm that point melt and yield rates often exceed the current design rate for winter probable maximum flood estimation. The model provides a basis for operational snowmelt flood forecasting. (Author's abstract)

FLOOD FREQUENCY ANALYSIS FOR SMALL WATERSHEDS IN SOUTHERN ILLINOIS,
Southern Illinois Univ. at Carbondale. Dept. of Forestry.
S.-K. Chong, and S. M. Moore.
Water Resources Bulletin, Vol. 19, No. 2, p 277-282, April, 1983. 8 Fig, 2 Tab, 12 Ref.

Descriptors: *Flood frequency, *Gaging stations, *Small watersheds, *Illinois, Flood peak, Hydrologic data, Regression analysis.

Twenty-two gaging stations were selected for developing a regional flood frequency curve for small (area less than 2 square miles) watersheds in southern Illinois. Five probability functions were compared, and the extreme value type I function was selected to develop the regional flood curve. The curve was generated with the index flood method and also another empirical method that related the function parameters to the watershed area. Estimated peak discharges with various return periods were compared with the results obtained from multiple regression analysis. (Author's abstract)

SIMULATING SOIL WATER RECESSION COEFFICIENTS FOR AGRICULTURAL WATERSHEDS,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
B. J. Choudhury, and B. J. Blanchard.
Water Resources Bulletin, Vol. 19, No. 2, p 241-247, April, 1983. 5 Fig, 1 Tab, 34 Ref.

Descriptors: *Agricultural watersheds, *Antecedent precipitation index, *Soil water, Agricultural runoff, Evapotranspiration, Remote sensing, Satellite technology, Mathematical models, Simulation, Recession.

The antecedent precipitation index (API) has been a useful indicator of soil moisture conditions for watershed runoff calculations, and recent attempts to correlate this index with spaceborne microwave observations have been fairly successful. The prognostic equation for soil moisture used in some of the atmospheric general circulation models (GCM) together with Thornthwaite-Mather parameterization of actual evapotranspiration leads to API equations. The recession coefficient for API is found to depend on climatic factors as contained in potential evapotranspiration and to depend on soil texture as reflected by field capacity and permanent wilting point. A recently developed model for global insolation is used with climatological data for Wisconsin to simulate the annual trend of the recession coefficient. Good quantitative agreement is shown with the observed trends at Fennimore and Colby watersheds in Wisconsin. This study suggests that API could be a unifying concept for watershed and atmospheric general circulation modeling. (Author's abstract)

Descriptors: *Stream discharge, *Soil-water-plant relationships, *Hawaii, *Forest hydrology, Forest watersheds, Precipitation, Rainfall-runoff relati
ships, Water quality, Ohia.

Dieback of the ohia forest over a large part of
Hilo watershed and adjacent areas has resulted
severe loss of the overstory crown component
the vegetation. The decline could cause seri
damage to the watershed. To evaluate poss
changes in conditions in the Hilo area since
decline began, stream flow, water quality,
precipitation data from 1929 to 1980 were coll
ed and analyzed. The limited data available do
indicate that the ohia decline has resulted i
significant change in either annual stream flow
peak stream flow of a stream discharging from
ohia forest in the Hilo area. Suspended sedim
production of two streams remains well wit
accepted levels as does the chemical makeup
components dissolved in the streams. (Autho

rado, *Stream discharge, Dissolved solids, Irri
tion effects, Supplemental irrigation, Draina
Leaching.

The salinity of the lower South Platte River
Colorado is characterized by plotting the avera
annual flow, total dissolved solids, and salt m
flow against distance along the stream. The pl
show that salts are being leached from the irrigat
lands above Greeley and are being deposited
the irrigated lands below Greeley. The salt depo
tion on the lower lands will result in their salin
tion. The plots show also that fall and wint
stream flows carry most of the salt loads. The
fall and winter flows are stored in off strea
reservoirs for use during the irrigation seaso
Therefore these salts are transferred to the low
irrigated lands where they accumulate. The s
balance for these lands can be improved by perm
ting the fall and winter flows to leave the basin,
by providing adequate land drainage coupled wi
supplemental irrigation water. (Author's abstrac

**TECHNIQUE TO RECONSTRUCT RIVER DI
CHARGE HISTORY FROM TREE-RINGS,**
Illinois State Water Survey, Champaign. Clim
tology and Meteorology Section.
W. M. Wendland, and D. Watson-Stegner.
Water Resources Bulletin, Vol. 19, No. 2, p 17
181, April, 1983. 2 Fig, 4 Tab, 16 Ref.

Descriptors: *Dendrochronology, *Stream di
charge, *Flood plains, Dating, Paleoclimatolog
Flood frequency, Precipitation, Mathematic
model.

Cores were obtained from several tree species l
cated both on a river floodplain and a nearb
terrace. A ratio of annual tree growth of floo
plains to terrace growth was developed and show
to be related to the annual river discharge. Growt
ratios from the time prior to written records ca
therefore be used to reconstruct river discharg
and infer past unrecorded flood frequency. Oa
and basswood ratios yielded the best models fo
discharge reconstruction, whereas those of elm an
birch were less useful. This method permits recon
struction of river discharge from an assemblage o
growth cores obtained within a relatively sma
area. (Author's abstract)

ESTIMATING A REGIONAL FLOOD FREQUENCY DISTRIBUTION,
Cornell Univ., Ithaca, NY. Dept. of Environmental Engineering.
J. R. Stedinger.
Water Resources Research, Vol. 19, No. 2, p 503-510, April, 1983. 5 Fig, 2 Tab, 34 Ref.

Descriptors: *Flood frequency, *Flood flow, Peak flow, Mathematical models, Statistical analysis.

When floods at different sites are assumed to arise from the same distribution except for scale (U.S. Geological Survey's Index Flood Method), one can attempt to identify the dimensionless flood-flow frequency distribution by normalizing small samples by each sample's sample mean. Unfortunately, the resultant curve may be a poor description of the true dimensionless flood distribution. This problem can be overcome by working with the logarithms of the peak flow values and using unbiased moment or probability weighted moment estimators. However, the correlation among concurrent flood flows in a region is shown to place severe limits on the accuracy with which a distribution's moments can be estimated with many such correlated records. DESIGN EVENTS WITH SPECIFIED FLOOD RISK,
Cornell Univ., Ithaca, NY. Dept. of Environmental Engineering.
J. R. Stedinger.
Water Resources Research, Vol. 19, No. 2, p 511-522, April, 1983. 4 Fig, 3 Tab, 76 Ref. CME8010889.

Descriptors: *Flood flow, Design floods, Statistical analysis, Probability, Flood plain management, Flood damage.

A maximum likelihood or method of moments estimate of the 99 percentile of a flood flow distribution is the traditional choice for the 100-year design flood event in flood plain planning. Because such estimates ignore the small-sample properties of quantile estimators, the resulting design event values will be exceeded with a probability in excess of that intended. For a sample size of 16 the estimated 100-year flood is, in expectation, the 50-year flood. Bayesian and classical statistical approaches can be used to develop design flood values which, given available hydrologic information, will (on average) be exceeded with the specific 1% design probability. Bias in estimates of expected flood damages and procedures for using regional information at gauged and ungauged sites are discussed. (Author's abstract)

ANALYTICAL SOLUTION FOR TRANSIENT TWO-DIMENSIONAL UNCONFINED GROUNDWATER FLOW,
Auckland Univ. (New Zealand). Dept. of Civil Engineering.
V. U. Nguyen, and A. J. Raudkivi.
Hydrological Sciences, Vol. 28, No. 2, p 209-219, June, 1983. 3 Fig, 1 Tab, 12 Ref.

Descriptors: *Differential equations, *Groundwater movement, Water table fluctuations, Laplace equation, Seepage, Flow rates, Mathematical studies.

An analytical solution of the differential equations describing the transient unconfined groundwater flow into a large cut such as an open strip mine is described. The free surface boundary of flow is time dependent and is not known beforehand. Discharge comes from the elastic storage and also from the lowering of the water table. The solution is based on a Laplace type formulation and provides, with the aid of the enclosed numerically evaluated functions, a quick and easy method of estimation of the phreatic surface and the flow rate as a function of time. Under certain conditions the solution approximates that based on the Dupuit approximation which neglects the vertical mass transport and puts the horizontal velocity proportional to the slope of the free surface. HP41C AND T159 PROGRAMS FOR ANISOTROPIC CONFINED AQUIFERS,
Kansas Univ., Lawrence.
A. D. Parr, J. G. Melville, and F. J. Molz.
Ground Water, Vol. 21, No. 2, p 212-220, March-April, 1983. 7 Fig, 4 Tab, 7 Ref.

Descriptors: *Permeability coefficient, *Confined aquifers, *Drawdown, *Computer programs, Pumping tests, Anisotropy, Mathematical studies.

Programs are presented for the HP41C and T159 programmable calculators for determining the ratio of horizontal to vertical hydraulic conductivity in anisotropic confined aquifers from pumping test data or for calculating drawdown given the aquifer parameters. The programs, based on Hantush's drawdown equations, eliminate the need to perform triple interpolation in obtaining the drawdown correction factor. By specifying a range of conductivity ratios, they can be used to solve the inverse problem given the drawdown data for a single observation well and the transmissivity and storage coefficient of the aquifer. The programs are illustrated by examples using the drawdown data from a pumping test performed in an anisotropic confined aquifer near Mobile, Alabama. (Moore-IVI)

GROUND-WATER MODELING WITH AN INTERACTIVE COMPUTER,
Idaho Univ., Moscow. Dept. of Agricultural Engineering.
G. L. Bloomsburg, and R. E. Rinker.
Ground Water, Vol. 21, No. 2, p 208-211, March-April, 1983. 3 Fig, 2 Ref. J0100013.

Descriptors: *Computer models, *Groundwater movement, *Mine drainage, Computer programs, Simulation, Saturated flow, Mine hydrology.

A large finite element program has been adapted to a PDP-11/23 minicomputer to obtain the advantages of an interactive computer system. The program used is UNSAT2, a code for unsteady, saturated and/or unsaturated flow of ground water. Some of the advantages of this interactive system are: ease of data input by the use of a digitizer; the opportunity to review all output files and to select for printing only those of interest; and the opportunity to change the physical boundaries of a problem at any desired time to make use of new information as a project progresses. This feature is particularly useful in mine-related water inflow predictions. This characteristic facilitates the simulation of flow into a vertical mine shaft as the shaft is being developed. To demonstrate the versatility of the program, it was used to simulate flow into a vertical mine shaft being developed in the Piceance Basin of Colorado. The major disadvantage is increased computational time. However, this disadvantage may not be particularly great because many organizations are not required to cost-account time on a minicomputer whereas this may not be the case for large machines. NOORDBERGUM EFFECT AND CHARACTERIZATION OF AQUITARDS AT THE RIO MAIOR MINING PROJECT,
Laboratorio Nacional de Engenharia Civil, Lisbon (Portugal).
J. D. Rodrigues.
Ground Water, Vol. 21, No. 2, p 200-207, March-April, 1983. 8 Fig, 1 Tab, 11 Ref.

Descriptors: *Aquitards, *Sand aquifers, *Permeability coefficient, Pumping tests, Water level, Noordbergum effect, Drawdown, Portugal, Rio Maior Basin.

The planned exploitation of the Rio Maior lignite deposits will require a major dewatering program involving a thick leaky sand aquifer, and a heterogeneous and anisotropic aquitard complex. Diatomite, lignite, and clay are the main lithologies found in this aquitard complex. Characterization of the sand aquifer was accomplished by performing pumping tests with interpretations for steady-state and nonsteady-state conditions. Aquitards were characterized by using both laboratory and field tests to determine hydraulic conductivity. Field methods were either those commonly adapted to leaky aquifers using water-level data taken from observation wells tapping the underlying sand aquifer or those using water-level data taken from piezometers located at the same distance from the pumping well and screened in the aquitard and in the aquifer. Field values of hydraulic conductivity are greater than laboratory values. In several piezometers the Noordbergum effect was observed during pumping tests. Redistribution of the loads originated by the pumping in the underlying sand aquifer is considered to be responsible for the reverse water-level response in the overlying lignite-diatomite complex. The Noordbergum effect has some influence in the application of the ratio method. On a practical basis, it seems reasonable to use the Noordbergum effect to compute drawdowns in the aquitards, and this leads to somewhat higher values for vertical hydraulic conductivities. HYDROGEOLOGY OF PIPELINE CANYON, NEAR GALLUP, NEW MEXICO,
New Mexico Health and Environment Dept., Santa Fe. Environmental Improvement Div.
R. R. Raymondi, and R. C. Conrad.
Ground Water, Vol. 21, No. 2, p 188-198, March-April, 1983. 7 Fig, 5 Tab, 12 Ref.

Descriptors: *Geohydrology, *Alluvium, Infiltration, Mine drainage, Groundwater recharge, Groundwater movement, Groundwater pollution, Water quality, Sodium, Sulfates, Geologic fractures, New Mexico, Pipeline Canyon.

The principal water-bearing units (in descending stratigraphic order) in Pipeline Canyon are the alluvium, the Dilco Coal Member of the Crevasse Canyon Formation, the Torrivio Sandstone Member of the Gallup Formation, and the Upper and Lower Gallup Sandstones. Presently, the alluvium is recharged by a perennial, southward-flowing stream sustained by mine dewatering discharge in addition to natural precipitation and runoff. Localized infiltration has created ground-water mounds in the alluvium. Artesian conditions may exist in sandstone units which are adjacent and hydraulically connected to the alluvium in these areas. Basement faults have produced the Fort Wingate and Pipeline Canyon lineaments which intersect in the area of investigation. Fault-related fracturing of the sandstones allows for significant ground-water recharge via the overlying alluvium. Flow in the sedimentary formations is generally to the northeast, while the alluvial system flows to the southwest. The natural water quality for the aquifers in the area is dominated by sodium and sulfate ions. However, complete characterization of the natural water quality is complex because of ground-water contamination by acidic tailings fluids from a local uranium mill. (Author's abstract)

Descriptors: *Permeability coefficient, *Mathematical models, *Groundwater movement, Water table, Groundwater recharge, Geohydrology, Geothermal resources, Volcanoes, Hydrologic budget, Meager Mountain, Vancouver, British Columbia

Meager Mountain is a recently-active andesite-dacite volcano situated 160 km NNW of Vancouver, British Columbia. The mountain is presently being jointly evaluated by the Geological Survey of Canada and the British Columbia Hydro and Power Authority as a potential geothermal resource. Limited existing and field-generated geological and hydrogeological data were employed to evaluate the ground-water flow regime at the study area. Mathematical modeling was carried out to determine the feasible range of ground-water-flow characteristics in the area. Field observations indicate that the water table is located at an intermediate elevation in the mountain system with the discharge area confined to the portion of the valley covered by unconsolidated deposits. Water balance calculations for the Lillooet River basin and base-flow determinations in the Meager Creek basin indicated that 14 to 17% of the total precipitation recharges the ground-water system. Various possible geological configurations were mathematically modeled with the water-table configuration and recharge rates restricted to the above ranges. The model results were used to predict the variations in the hydraulic conductivity in each geological formation. The results fell into a discrete range of values thought to be within an order of magnitude of the actual values. (Author's abstract)

GROUNDWATER FLOW AND IMPLICATIONS FOR GROUNDWATER CONTAMINATION NORTH OF PREWITT, NEW MEXICO, U.S.A.,
New Mexico Inst. of Mining and Technology, Socorro. Dept. of Geoscience.
D. B. Stephens.
Journal of Hydrology, Vol. 61, No. 4, p. 391-408, March, 1983. 8 Fig, 2 Tab, 23 Ref.

Descriptors: *Groundwater movement, *Groundwater pollution, *New Mexico, Geohydrology, Permeability coefficient, Groundwater recharge, Topography, Aquitards, Mathematical models, Path of pollutants.

In the southern San Juan Basin, New Mexico, strata of Permian and younger age dip gently toward the center of the basin. Most previous investigators believed that recharge to these strata occurred by precipitation on the outcrops and groundwater flowed downdip to the north and northeast. Recent water-level measurements in an undeveloped part of the basin near Prewitt, New Mexico, show that groundwater at shallow depths in alluvium and bedrock flows southward, opposite to the dip direction, and toward a major ephemeral drainage in a strike valley. North of this area, groundwater in deep bedrock aquifers does appear to flow northward. This information suggests that there are two groundwater circulation patterns; a shallow one controlled by topography and a deeper one controlled by geologic structure. Significant amounts of recharge to sandstone aquifers by infiltration through outcrops is unlikely due to the near-vertical exposures on cliffs, the gentle dip of the strata, and small annual precipitation. Numerical model results suggest that recharge to bedrock aquifers may be from downward leakage via aquitards over large areas and leakage from narrow alluvial aquifers in the subcrop area. The recharge mechanism is controlled by the hydraulic conductivity of the strata. As the flow path is controlled by hydraulic conductivity contrasts, geologic structure, and topography, contamination movement from surface impoundments is likely to be difficult to predict without a thorough hydrogeolical site investigation. tion, *Hydrodynamic dispersion, Mathem
studies, Dispersion, Solute transport, Tracers,
eholes.

Groundwater velocity and hydrodynamic di
sion coefficients can be determined simultane
from observed data of solute concentration a
center of a single borehole. Two types of as
totic analytical solutions to the convection-di
sion equation were proved to be applicab
analyze single borehole dilution tests. In ord
calculate the groundwater velocity, and the l
tudinal and transverse dispersion coefficien
three unknown variables in the asymptotic
tions, Powell's optimization method was appli
several cases together with the optimiz
method of Fletcher and Powell. The results o
application of these two optimization metho
several assumed sets and one actual experim
set of tracer concentrations showed that Pow
method based upon a conjugate direction p
dure without calculating derivatives is more
able, more flexible and much faster in conver
to the true values than the method of Flet
Powell, which is based on a conjugate gra
procedure utilizing both criterion functions
their first derivatives. Furthermore, when Pow
optimization method was applied together wit
proposed asymptotic solution to single bore
dilution data measured in field, the obtained v
of the groundwater velocity, and the longitu
dispersion coefficients were quite reasonable.

OTE ON FRACTURE FLOW DISPERSION CHANISMS IN THE GROUND,
l Inst. of Tech., Stockholm (Sweden). Dept. hemical Engineering.
retnieks.
r Resources Research, Vol. 19, No. 2, p 364- April, 1983. 5 Fig, 2 Tab, 32 Ref.

Descriptors: *Geologic fractures, *Dispersion coefficient, Stratified flow, Diffusion, Sorption, Tracers, Channeling, Mathematical models.

Two mechanisms for spreading of a tracer pulse in fissured media are discussed: channeling and diffusion in the rock matrix. Dispersion has traditionally been treated as a random mechanism, comparable to diffusion. It is not quite clear if this is applicable to such geologic media as sparsely fissured rock or other stratified media. In this paper, two other mechanisms for dispersion are treated. One is stratified flow; the other is due to interaction with a solid material. A very idealized case of stratified flow is treated. A case is modeled where the medium flows in parallel channels. Each channel is assumed to consist of the space between two parallel plates. The flow is laminar. The various channel widths are assumed to be randomly distributed with a lognormal frequency distribution. This is a distribution which has been found experimentally in fissured crystalline rock. For this case, it is shown that an equivalent dispersion coefficient will increase with the distance between injection and observation point. For this case the normal Fickian diffusion dispersion description is not applicable if the usual assumption is made that the dispersion coefficient is constant. There are several interaction mechanisms of interest between a solute and the solid material. The one treated here is the diffusion of the solute into the porous rock matrix and sorption of the inner surfaces of the matrix. This interaction will also lead to the spreading of a tracer front, in a similar way to what other dispersion mechanisms do. It is demonstrated that if the solid material has very long extension, the dispersion due to this mechanism is so large that a Fickian dispersion coefficient cannot be evaluated without explicitly accounting for this mechanism. Attempts to evaluate Fickian dispersion coefficients by the method of moments will give values which are entirely dependent on the observation accuracy of the tail. (Author's abstract)

THEORY OF EARTH TIDE AND BAROMETRIC EFFECTS IN POROUS FORMATIONS WITH COMPRESSIBLE GRAINS,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
G. van der Kamp, and J. E. Gale.
Water Resources Research, Vol. 19, No. 2, p 538-544, April, 1983. 1 Tab, 29 Ref.

Descriptors: *Pore pressure, *Earth tide, *Barometric effects, Groundwater movement, Geohydrology, Tides, Mathematical models, Stress, Strain.

The general three-dimensional equations for pore pressure, stress, and strain in a homogeneous porous medium with compressible grains are used to derive expressions for the response of fluid pressure to the stress changes due to earth tides and barometric loading effects. The analysis constitutes a generalization of earlier derivations. The formation is assumed to be of large extent laterally so that horizontal flow may be neglected. It is shown that vertical flow induced by the pore pressure changes can be analyzed by means of a diffusion equation. An expression for the specific storage coefficient is derived which is valid if horizontal deformations are negligible and which includes the effect of the compressibility of the solid grains. Measurements of earth tide and barometric effects constitute two in situ tests of bulk formation properties. Such measurements can therefore make an important contribution to the characterization of the hydraulic and elastic properties of a particular formation. (Author's abstract)

GROUNDWATER GEOCHEMISTRY AND CALCITE CEMENTATION OF THE AQUIA AQUIFER IN SOUTHERN MARYLAND,
Geological Survey, Towson, MD. Water Resources Div.
F. H. Chapelle.
Water Resources Research, Vol. 19, No. 2, p 545-558, April, 1983. 9 Fig, 2 Tab, 21 Ref.

Descriptors: *Groundwater, *Calcite, *Minerals, *Chemical composition, Aquia Aquifer, Maryland, Calcium, Manganese, Bicarbonate, Sodium, Aquifer characteristics, Cementation, Mathematical models.

The Aquia aquifer in southern Maryland exhibits three regions that are characterized by distinctly different water composition. Region I is about 42 km wide and is parallel to the outcrop area. Water in region I has relatively high calcium, magnesium, and bicarbonate concentrations and relatively low sodium concentrations. Region II, parallel to and downgradient from region I, is about 38 km wide. Water in region II is characterized by constant bicarbonate, increasing sodium, decreasing calcium, and decreasing magnesium concentrations. Region II is downgradient from region II and is characterized by low calcium, low magnesium, high bicarbonate, and high sodium concentration. The major lithologic constituents of the Aquia aquifer are quartz sand (about 55%), glauconite (about 30%), and carbonate shell material (about 8%). Heavy minerals, clay minerals, finely disseminated lignite make up about 2% of the aquifer material. Calcite cementation is commonly observed in and near the outcrop area of the Aquia. Stoichiometric chemical models were constructed based on this lithology to described the water chemistry of each region. The applicability of these models was verified by comparing predicted and observed molar ratios of dissolved species using linear regression techniques. In all cases, close matches were found between predicted and measured curves. Mass balance calculations using the verified chemical models predict a spatial distribution of calcite cementation that closely matches the observed distribution in the Aquia aquifer. This suggests that the observed calcite cementation is postdepositional in origin and has resulted from reaction of groundwater with aquifer material. (Author's abstract)

ANALYTICAL SOLUTION OF A PARTIALLY PENETRATING WELL IN A TWO-LAYER AQUIFER,
California Univ., Berkeley. Lawrence Berkeley Lab.
I. Javandel, and P. A. Witherspoon.
Water Resources Research, Vol. 19, No. 2, p 567-578, April, 1983. 7 Fig, 19 Ref. DE-AC03-76SF00098.

Descriptors: *Partially penetrating wells, *Layered aquifers, Pumping tests, Mathematical studies, Drawdown, Well yield.

The behavior of a two-layer aquifer pumped by a partially penetrating well is a matter of considerable interest. Analytical solutions are developed for drawdowns in either layer and are evaluated numerically to illustrate some typical cases. The validity of the solutions is demonstrated by comparison with the limiting single-layer case and with results from finite element calculations. Asymptotic solutions for small and large values of time are developed to show that (1) at early times with partial penetration the behavior of the pumped layer is exactly the same as that of a single layer and (2) at large values of time a semilog plot of drawdown versus time yields a straight line whose slope is only a function of the sum of the two transmissivities. A method is proposed for the interpretation of pump test data. (Author's abstract)

2G. Water In Soils

ISOTOPIC INVESTIGATION OF A NEAR-SURFACE GROUNDWATER SYSTEM,
Heidelberg Univ. (Germany, F.R.). Inst. fuer Umweltphysik.
S. K. Gupta.
Hydrological Sciences Journal, Vol. 28, No. 2, p 261-272, June, 1983. 4 Fig, 12 Ref.

Descriptors: *Tritium, *Deuterium, *Oxygen isotopes, *Groundwater dating, Precipitation, Radioisotopes, Mathematical models, Environmental tracers, Evapotranspiration, Aquifers, Aeration zone, *Isotope, Soil moisture, German Federal Republic, Rhine Valley.

The distribution of environmental tritium, deuterium and oxygen-18 in the unsaturated zone and the underlying sandy phreatic aquifer was studied throughout 1981 in an area of high pine forests in the Rhine valley near Heidelberg. The observed vertical distribution of isotopes in the unsaturated zone can be satisfactorily explained by the combined use of a multi-cell model for moisture transport and an evapotranspiration model. The distribution in the underlying aquifer of the tracer input at the water table obtained using this method is found by replacing the total vertical diffusion coefficient in the diffusion equation with the dispersion coefficient. In this way observed tritium profiles are satisfactorily simulated for the period 1966-1981. The stable isotope profile in the unsaturated zone however remains largely unexplained due to inadequate data on the stable isotope content of precipitation over the investigated area. OPTIMUM MOISTURE CONTENT FOR COMPACTING SOILS: ONE-POINT METHOD,
Irrigation Research Inst., Lahore (Pakistan).
I. H. Hamdani.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 2, p 232-237, June, 1983. 3 Fig, 1 Tab, 3 Ref.

Descriptors: *Cohesive soils, *Soil compaction, Soil water, Soil density, Mathematical studies.

A one-point method for finding out Proctor Standard compacted maximum dry density and optimum moisture content of cohesive soils has been developed. It omits the usual laborious procedure of compaction test and requires only the determination of dry density of soil at 9% moisture content from which the maximum dry density and thereafter optimum moisture content can be found out. The method, therefore, shortens the time for the determination of the variables viz. maximum dry density and optimum moisture content for any given soil. On the basis of experimental data collected at the Irrigation Research Institute, Lahore (Pakistan), some mathematical relationships have been developed to compute the value of maximum dry density and optimum moisture content based on dry density of soil compacted at 9% moisture in a Proctor mold. ASSESSMENT OF EVAPORATION FROM BARE SOIL BY INFRARED THERMOMETRY,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
J. Ben-Asher, A. D. Matthias, and A. W. Warrick.
Soil Science Society of America Journal, Vol. 47, No. 2, p 185-191, March-April, 1983. 5 Fig, 2 Tab, 15 Ref.

Descriptors: *Soil water, *Evaporation, Wind speed, Infrared thermometry, Energy, Infrared imagery, Remote sensing.

A method is described to estimate daily soil water evaporation from a drying uniform bare soil. The method involves wind speeds (u) and midday infrared thermometric measurements of surface temperatures of the drying soil (Td) and a nearby reference dry soil (To). Calculation of evaporation is made using a linear function of (To-Td) and u derived from basic energy balance considerations. An experiment was conducted in Tucson, Arizona, to compare lysimeter-measured values of evaporation with those estimated on the basis of the method. Three lysimeters (0.5 by 0.5 by 0.12 m) containing uniform soil were used in this experiment. One was kept wet (steady-state saturation), one was air dry, and one was initially wetted and allowed to dry during a 21-d interval in December 1981. Results showed a good agreement, $r(2)=0.61$, between the theoretical and measured values. The method is proposed for use in studies of field variability of soil water evaporation and is amenable to the utilization of remotely sensed data. (Author's abstract)

PHENOLOGICAL PATTERNS OF CHIHUAHUAN DESERT PLANTS IN RELATION TO THE TIMING OF WATER AVAILABILITY,
New Mexico State Univ., Las Cruces. Dept. of Biology.
P. R. Kemp.
Journal of Ecology, Vol. 71, No. 2, p 427-436, July, 1983. 2 Fig, 2 Tab, 40 Ref.

Descriptors: *Available water, *Desert plants, *Phenology, Timing, Species diversity, Photosynthesis, Seasonal variation, Soil water, Drought, Grasses, Forbs, Shrubs, Precipitation.

Phenology, density, and cover of plant species occurring in a single Chihuahuan desert habitat were studied for 2 yr as a function of habitat moisture with the objective of relating plant species diversity to water partitioning. Much of the temporal variation in growth and phenology between species was correlated with differences in life form and photosynthetic pathway. The annual plant species consisted of a winter-spring group containing only species with the C3 photosynthetic pathway which utilize the moisture from frontal storms of winter, and a summer group containing a large majority of species with the C4 photosynthetic pathway which utilize the moisture from convectional storms of late summer. The perennial plant species consisted of C3 and C4 forbs, C4 grasses, C3 shrubs and CAM shrubs. The C3 forbs showed greatest activity in spring or autumn while the C4 forbs and grasses were most active in the summer and autumn. The C3 shrubs and CAM shrubs were active at various times from spring to autumn and not as dependent as the other groups on available soil moisture. There was above average precipitation in late summer and autumn during the first year of study and an early and prolonged drought in autumn of the second year. Some species of perennial C3 forbs and C4 grasses responded to the abundant precipitation of the first autumn with increased density or cover in the second year, but there was little change in the shrub species. The drought in the second year caused a reduction in the number of species and individuals of both C3 and C4 annual plants. The results suggest that the high species diversity in this habitat is partly a result of the different life form and photosynthetic pathway groups, each being adapted for utilizing a particular phase of the seasonally and yearly variable water. ELEMENTS RETURNED TO FOREST FLOOR IN TWO RAINFOREST AND THREE PLANTATION PLOTS IN TROPICAL AUSTRALIA,
Commonwealth Scientific and Industrial Research Organization, Hobart (Australia). Div. of Forest Research.
H. M. Brasell, and D. F. Sinclair.
Journal of Ecology, Vol. 71, No. 2, p 367-378, July, 1983. 2 Fig, 6 Tab, 40 Ref.

Descriptors: *Rainfall, *Cycling nutrients, Potassium, Calcium, Magnesium, Sodium, Litter, Rain forests, Forest soils.

Returns of potassium, calcium, magnesium and sodium to the forest floor in rainfall, throughfall, litterfall and branchfall were compared for tropical rainforest and adjacent plantations of Araucaria cunninghamii at two sites with contrasting rainfall and soil fertility. At one site a plantation of Flindersia brayleyana was also compared. At each site, the input of potassium was highest in the rainforest plots. The addition of sodium was higher at the wetter site, and was mostly derived from rainfall. Estimates of the loss of dry weight and elements from the litter layer, based on the relationship between litterfall and the standing crop of litter on the forest floor, were greater in the rainforest plots than in the Araucaria plantations. The annual [illegible] of litter disappearance (k, the quotient of annual litterfall to the mean amount of litter on forest floor) ranged from 0.69 for the Araucaria plot to 1.25 for the rainforest plot at the same [illegible] (Author's abstract)

BEHAVIOR OF CHROMIUM IN SOILS. INTERACTIONS BETWEEN OXIDATION-REDUCTION AND ORGANIC COMPLEXATION
Vermont Agricultural Experiment Station, Burlington.
B. R. James, and R. J. Bartlett.
Journal of Environmental Quality, Vol. 12, No. 2, 173-176, April-June, 1983. 5 Fig, 2 Tab, 7 R

Descriptors: *Tannery wastes, *Chromium, *Solubility, *Chelation, *Manganese, Toxicity, Oxidation.

Initial oxidation rates of different forms of Cr(III) added to an Aquic Udorthent soil, and the maximum Cr(VI) levels observed, decreased in the order: freshly-precipitated Cr(OH), is greater than Cr-citrate is greater than aged Cr(OH)3. The oxidation of Cr(III) in tannery sewage sludge and tannery effluent added to a Typic Eutrochrept soil also was studied as a function of time and loading rate. Amounts of Cr(VI) formed increased with Cr(III) added from 0.025 to 6.2 mmol per 100 g soil (29 to 7,200 kg per ha) for sewage sludge Cr(III), and from 0.1 to 1.8 mmol per 100 g soil (103 to 2,100 kg per ha) for the tannery effluent Cr(III). Levels of water-soluble Cr(VI) increased for a month in most of the treatments, despite the presence of reducing agents in the soil and in the wastes. Adding citric acid to the soil along with the tannery wastes increased the amount of Cr(VI) formed at each treatment level, and decreased the Cr(III) loading rate required for observation of oxidation. Mutual facilitation of Cr(III) oxidation by chelation and of further chelation by oxidation was postulated as a possible mechanism for the continuous formation of Cr(VI) in a soil. The reduction of soluble Cr(VI) in unlimed (pH 5.) and limed (pH 6.5) samples of an Ultic Hapludalf resulted in the formation of soluble organic complexes of Cr(III) if citric acid was added with the Cr(VI). During a 9-d incubation period, more reduction of Cr(VI) occurred in unlimed than limed samples, but higher levels of soluble Cr(III) chelate were measured in the limed treatment. Increasing the ratio of citrate to Cr(VI) increased the rate of reduction of the CR(VI) in the Aquic Udorthent. Soluble Cr(III)-chelate formed, and the length of time the Cr(III) remained soluble also increased with the citrate/Cr ratio. (Author's abstract)

VERTICAL INFILTRATION OF WATER INTO UNSATURATED SOILS WITH VARIABLE DIFFUSIVITY AND CONDUCTIVITY,
Thessaloniki Univ., Salonika (Greece). School of Technology.
P. K. Tolikas, D. K. Tolikas, and C. D. Tzimopoulos.
Journal of Hydrology, Vol. 62, No. 1-4, p 321-332, April, 1983. 2 Fig, 7 Ref.

Descriptors: *Soil water, *Infiltration, Diffusion coefficient, Permeability coefficient, Wetting front, Mathematical models.

A simple approximate analytical solution to the problem of vertical infiltration of water into unsaturated soils is presented. The soil-water diffusivity as well as the hydraulic conductivity are assumed to be exponential functions of the soil-water content. Constant-concentration conditions are assumed at the boundary. The infinite-domain problem is reduced to a finite-domain problem under the assumption of an abruptly terminating wetting front coinciding with the inflection point of the soil-water content profile. The location as well as the soil-water content at the inflection point are calculated and the result is employed for the approximate solution of the problem. Numerical results obtained by the theory of this paper are compared with those obtained by Philip's method.

is excellent agreement especially in the posi-
f the wetting front. (Moore-IVI)

movement of various chemicals in porous
ia with dispersion is of interest during reclama-
tion of saline soils. The hydrodynamic dispersion coefficient is one of the parameters used to predict the salt movement. A new approach is presented for determining the hydrodynamic dispersion coefficient, D. Equations were derived for predicting the leached fraction of salts for a particular salt-water system. Using these equations, relations for evaluating D for a step input and an initial state with uniformly distributed salts were derived and tested. The results indicate that predictions made using this approach are similar to earlier approaches. Also predictions of leached fractions of salts made using these parameters are in close proximity to observed values. (McKeon-IVI)

MODELING INFILTRATION INTO CRUSTED SOILS BY THE GREEN-AMPT APPROACH,
Agricultural Research Service, Durant, OK. Water Quality and Watershed Research Lab.
L. R. Ahuja.
Soil Science Society of America Journal, Vol. 47, No. 3, p 412-418, May-June, 1983. 4 Fig, 19 Ref.

Descriptors: *Soil surfaces, *Infiltration, *Soil crusts, Interfaces, Mathematical models, Soil water, Hydraulic resistance, Soil saturation, Unsaturated flow.

The study deals with infiltration of water through a stable surface crust, wherein the water content at the crust-soil interface increases with time for a long period, and remains below the saturated value. An approximate Green-Ampt-type formulation derived from a physical basis, containing a time-dependent capillary drive term and a profile shape factor, is evaluated by comparisons to a similarity solution and a finite-difference numerical solution of the problem. The exact nature of the derived Green-Ampt formulation is established for early to intermediate stages for certain reasonable conditions. Calculations of cumulative infiltration with time made by the above approach, with the profile shape factor set equal to unity, were within tolerable error from the numerical solution results for one soil and a set of experimental data for another. A previously reported piecewise application of the conventional form of the Green-Ampt equation is also developed to enable its use from time zero, as an independent predictive method. This method, which includes some implicit correction for the profile shape, gave slightly better calculations of the cumulative infiltration. The above simple methods should also be applicable to related unsaturated flow problems, such as infiltration through a transient crust-seal resistance and into a layered soil having a fine material overlying a course material. EXPERIMENTAL VERIFICATION OF A MODEL TO PREDICT SOIL MOISTURE AND TEMPERATURE PROFILES,
R. J. Lascano, and C. H. M. van Bavel.
Soil Science Society of America Journal, Vol. 47, No. 3, p 441-448, May-June, 1983. 8 Fig, 6 Tab, 26 Ref.

Descriptors: *Soil water, *Soil temperature, Mathematical models, Simulation, Energy, Spatial variability, Soil layers.

A model was used to calculate water and temperature profiles over 30 d for a bare soil profile, using the hydraulic characteristics of the soil and standard meteorological data as input. The model was also used to determine the spatial variability of the calculated values, using the concept of similar media. The calculated profiles were compared to actual measurements, made periodically over the same period of time. The predicted water content values for different soil layers were within 1 standard deviation of the average measured values. The predicted temperature profiles were within 1 C of the measured values. The estimate of the spatial variability of the calculated values of water content was comparable to the variance of the measured values. Hence, it is concluded that the model was adequate to its purpose, under the conditions of the verification made. (Author's abstract)

INFLUENCE OF VELOCITY ON HYDRODYNAMIC DISPERSION DURING UNSTEADY SOIL WATER FLOW,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Environmental Mechanics.
W. J. Bond, and D. E. Smiles.
Soil Science Society of America Journal, Vol. 47, No. 3, p. 438-441, May-June, 1983. 2 Fig, 14 Ref.

Descriptors: *Hydrodynamics, *Unsteady flow, *Soil water, Mathematical studies, Velocity, Dispersion, Unsaturated flow, Solute transport, Constant flux absorption, Soil adsorption capacity.

A recent solution of the equation for hydrodynamic dispersion during unsaturated, unsteady soil water flow is extended to include the velocity dependence of the dispersion coefficient. The effect of this velocity dependence on the solute concentration profiles is illustrated for the case of horizontal constant concentration absorption of water by an initially dry soil. The application of the theory to other soil water flow situations, including constant flux absorption, is also examined. (Author's abstract)

LEACHING CHARACTERISTICS OF A STONY DESERT SOIL,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Inst. of Soil and Water.
D. Russo.
Soil Science Society of America Journal, Vol. 47, No. 3, p 431-438, 1983. 6 Fig, 2 Tab, 27 Ref.

Descriptors: *Leaching, *Desert soils, *Soil water, *Pressure potential head, Permeability coefficient, Infiltration rate, Conductivity, Soil solution, Dispersion, Stony soils.

The leaching characteristics of a stony desert soil were studied. The functional relationships between pressure potential head and gravimetric water content for the different soil layers were determined in the laboratory under drying conditions using samples in which the stony fractions (>2 mm) were excluded. These gravimetric water content values were converted to field volumetric water contents, using the field-measured values of the field bulk density and the stone fraction (on a mass basis). For a given pressure potential head, volumetric water content decreased with depth. Unsaturated soil hydraulic conductivity functions for the different soil depths were determined by the transient drainage profile method, using tensiometers and the appropriate soil water characteristics functions. The saturated hydraulic conductivities were estimated from the steady-state infiltration rate and the appropriate hydraulic head gradients. Measured saturated hydraulic conductivity values decrease with soil depth while for a given pressure potential head, the unsaturated hydraulic conductivity increases with depth. A leaching experiment was conducted in the field, by operating a sprinkler system at a rate of 7.6 mm/h. The time variations of the electrical conductivity (EC) of the soil solution as well as the concentrations of Na(+), Ca(2+), Mg(2+), Cl(-), and SO4(2-) were recorded by extracting soil solution samples from four soil suction probes located at a depth of 0.45 m and spaced 12 by 12 m apart. The initial average EC of 165 dS/m was reduced to 7.5 dS/m as 800 mm of water were applied to the soil. This final value of the EC of the soil solution is three times higher than the EC of the irrigation water, as a result of the presence of gypsum and relatively high ESP in the solid phase of the soil profile. Measured values of the EC of the soil solution were used to estimate the value of the dispersity for longitudinal dispersion, lambda. The resulting, lambda = 2.91 cm is in relatively good agreement with published field data of lambda for another soil, but is much smaller than the value of the equivalent field-scale dispersivity calculated for two different soils. SIMPLE MEASUREMENTS OF SOIL SURFACE MICRORELIEF CHARACTERISTICS,

South Dakota State Univ., Brookings. Dept. of Plant Science.
E. M. White.
Water Resources Bulletin, Vol. 19, No. 2, p 231-233, April, 1983. 1 Fig, 2 Tab, 4 Ref.

Descriptors: *Soil surfaces, *Topography, *Surface runoff, Surface water storage, Roughness coefficient, Natural slope, Microrelief.

Soil surface roughness and the topographic orientation of microrelief influence runoff and water storage. Distances measured following the surface of the microrelief and horizontally across the area with the microrelief can be used with the number of microridges or microhills to estimate the average cross-sectional areas of the depressions, the microslope angles, and crest heights. Microridge sideslope angles which affect the rate of runoff were estimated reasonably well in field plots by the method. (Author's abstract)

AQUIC MOISTURE REGIMES IN SOILS WITH AND WITHOUT LOW CHROMA COLORS,
Texas A and M Univ., College Station. Dept. of Soil and Crop Sciences.
M. J. Vepraskas, and L. P. Wilding.
Soil Science Society of America Journal, Vol. 47, No. 2, p 280-285, 1983. 6 Fig, 4 Tab, 17 Ref.

Descriptors: *Soil water, *Soil saturation, *Water table fluctuations, Redox potential, Chroma colors, Perched water table, Iron compounds, Groundwater, Aquic moisture regimes, Soil organic matter.

Four seasonally saturated Alfisols along a toposequence 56 km north of Houston, Texas, were studied to determine if each soil had an aquic moisture regime. Water table fluctuations were monitored weekly during 1978 and 1979, and oxidation-reduction (redox) potentials and groundwater Fe contents were monitored weekly during 1979 only. Water tables of soils on backslope and toeslope positions were perched and rose to the surface during periods of heavy rainfall. Water tables of lowland soils were probably permanent, and their rise lagged behind those of the uplands soils by as much as 3 months. Redox potentials ranged from -200 to +900 mV across the toposequence during the year. Anaerobic conditions existed in each soil for variable periods. The periods when redox potentials (at a depth of 75 cm) were sufficiently low to reduce Fe(III) compounds generally increased from 6 to > 197 cumulative days from upper to lower topographic positions. Groundwater Fe contents were low, ranging between 0.1 and 2.7 ppm . Apparently little Fe reduction occurs in this landscape, because organic matter levels are low (< 1.0%). On the basis of the water table and redox potential measurements, each soil was considered to have significant periods of saturation and reduction with 75 cm of the surface. Low chroma (< 2) colors were not found in horizons (at a depth of 75 cm) which were reduced for 120 cumulative days, but color chromas were 3 or less along ped surfaces and ped interiors had mottles with chromas of 4 or more. Limitations of the low (< 2) chroma color criterion commonly used to identify aquic moisture regimes are discussed. Recommendations for use of color chromas of 3 or less for identification of aquic moisture regimes are proposed. (Author's abstract)

A SOIL AND ATMOSPHERIC BOUNDARY LAYER MODEL FOR EVAPOTRANSPIRATION AND SOIL MOISTURE STUDIES,
Computer Sciences Corp., Silver Spring, MD.
P. J. Camillo, R. J. Gurney, and T. J. Schmugge.
Water Resources Research, Vol. 19, No. 2, p 371-380, April, 1983. 9 Fig, 5 Tab, 18 Ref. NAS5-24350.

Descriptors: *Soil water, *Evapotranspiration, *Computer models, Remote sensing, Energy, Soil temperature, Thermal conductivity, Aerodynamic roughness, Air-soil interfaces.

A computer model of the upper soil and lower atmosphere boundary layer has been developed for use with remotely sensed data. It includes both energy and moisture balances, and it uses a predictor/corrector integrator with an automatically changing time step; these two components make the model both stable and efficient. It is driven by surface heat and moisture fluxes computed from standard meteorological data. Remotely sensed surface temperature and soil moisture can be compared to model estimates for calibration. The model has been tested using 44 hours of data from a bare soil site. Using daily maximum surface temperatures for calibration, estimated hourly surface temperatures agreed with measurements to better than 1 K. The results are insensitive to the soil heat capacity and most sensitive to the thermal conductivity and aerodynamic roughness. By varying these within physically reasonable limits, bounds on daily evaporation of 3.2 mm and 3.8 mm were estimated. (Author's abstract)

ESTIMATING PROFILE WATER STORAGE FROM SURFACE ZONE SOIL MOISTURE MEASUREMENTS UNDER BARE FIELD CONDITIONS,
Lockheed Engineering and Management Services Co., Inc., Houston, TX.
L. M. Arya, J. C. Richter, and J. F. Paris.
Water Resources Research, Vol. 19, No. 2, p 403-412, April, 1983. 8 Fig, 2 Tab, 25 Ref.

Descriptors: *Profile water storage, *Soil water, Mathematical models, Simulation, Soil surfaces, Irrigation, Corn, Surface flux, Remote sensing, Cultivation.

A linear regression approach was used to estimate profile water storage from the storage in the surface zone. For a given thickness of the surface zone the correlations between the surface zone and profile water storages decreased as the profile depth increased; for a given profile depth, these correlations increased as the surface zone thickness increased. In general, the correlations were higher for irrigated corn fields than for bare fields. Results show that the profile depth for which water storage can be predicted from surface zone soil moisture data depends on the thickness of the surface zone, the cultural condition of the field, and the coefficient of determination considered adequate. An alternative procedure to estimate water storage in a deep profile under bare field conditions is based on the assumption that change in profile water storage over a period of time equals net surface flux over the same time. Surface fluxes are computed from surface zone soil moisture data and hydrologic properties of the soil. In a simulation study, net surface fluxes very nearly equaled changes in water storage of a 2.25-m-deep profile. For a field-measured data set, computed surface fluxes and those measured by a weighing lysimeter showed good overall agreement. (Author's abstract)

UNSATURATED FLOW IN SPATIALLY VARIABLE FIELDS; 1. DERIVATION OF MODELS OF INFILTRATION AND REDISTRIBUTION,
Tel-Aviv Univ. (Israel). School of Engineering.
G. Dagan, and E. Bresler.
Water Resources Research, Vol. 19, No. 2, p 413-420, April, 1983. 3 Fig, 16 Ref.

Descriptors: *Soil water, *Infiltration, *Redistribution, Mathematical models, Unsaturated flow, Permeability coefficient, Soil water suction, Water flux, Vertical flow.

Models of water flow in the upper soil layer of spatially variable fields are developed. Field variability is assumed to take place in the horizontal plane. The saturated hydraulic conductivity is assumed to be a random variable of lognormal distribution, and head suction and moisture content are related to it by simple analytical relationships. The aim of study is to derive the expectation and variances of the moisture content, suction heads, hydraulic conductivity, and water flux as functions of depth and time for infiltration and redistribution. Toward this aim a simplified solution of verti flow in a homogeneous column, based on the co cept of moving front, is developed. The statisti procedure for using this solution in a spatia variable field is outlined. (Author's abstract)

UNSATURATED FLOW IN SPATIALLY VAR ABLE FIELDS; 2. APPLICATION OF WATE FLOW MODELS TO VARIOUS FIELDS,
Agricultural Research Organization, Bet-Dag (Israel). Volcani Center.
E. Bresler, and G. Dagan.
Water Resources Research, Vol. 19, No. 2, p 42 428, April, 1983. 5 Fig, 12 Ref.

Descriptors: *Soil water, Unsaturated flow, Mat ematical models, Infiltration, Redistribution, Pe meability coefficient, Wetting front, Hydraul properties.

The method of modeling water flow during infi tration and redistribution formulated in part 1 this study has been applied to compute expecta tions and variances of a few water flow variable and of effective hydraulic properties. Two spatia ly variable soils with different degrees of variatio have been investigated. The expectations and va iances are obtained by using the statistical averag ing procedure and probability density functio (pdf) of saturated hydraulic conductivity Ks. Th stationarity hypotheses and the requirement tha the integral scale of Ks is much smaller than th length scale characterizing the field in the x, plane have been adopted. An approximate solutio which assumes the concept of a wetting front an uniform water content is used for the statistica averaging procedure. A comparison of these re sults with data computed by a more accurate nu merical solution to Richard's equation shows tha the approximate simplified models lead to a quit accurate value of the expectations and variances o the flow variables when the field is sufficiently heterogeneous. It is suggested that in spatially vari able fields, stochastic modeling represents th actual flow phenomena more realistically and pro vides the main statistical moments (mean, var iances) by using simplified flow models which ca be used with confidence in applications. The field effective hydraulic properties have been defined and derived by using approximate models. It is shown that effective properties may be meaningful only under very restricted and special conditions, such as steady gravitational flow. They do not exist in the general case of infiltration-redistribution. It is concluded that the traditional deterministic approach for solving the flow equations cannot be justified for solving flow problems in spatially variable fields. (Author's abstract)

Descriptors: *Solute transport, *Unsaturated flow, Soil water, Infiltration, Redistribution, Interstitial water, Wetting front, Salts, Mathematical models, Simulation.

An approximate model of salt transport in a spatially variable field during infiltration and redistribution is presented. The water flow is assumed to be vertical, and both pore water velocity and depth of wetting front change in the horizontal plane due to the variability of soil hydraulic properties. The salt transport in the vertical profile is computed by using an approximate, closed form solution of the convection-dispersion equation, with the value of the dispersivity increasing from zero to its maximum (3 cm) as the front propagates downward. The concentration profiles vary in the horizontal plane because of the aforementioned variation of water flow variables. The expectation value and the variance of the concentration are computed as

of depth and time for two variable soils
, with large variability, and Bet Dagan,
er variability). The results are compared
e based on a numerical simulation of the
w and salt transport, as well as with those
to an equivalent, deterministic, uniform
the expected value). The approximate
lds quite accurate results when compared
numerical simulations for the field of
riability, while some differences are
or the more uniform one. The results for
cted value, based on the traditional ap-
replacing the variable field by an equiva-
rm one, include a much larger error. In
the apparent complexity, the statistical
of salt concentration in a spatially vari-
can be determined by using simple flow
Therefore further refinement of models of
in homogeneous columns does not seem
ranted, and the research effort should be
ted on the study of field variability.

SILICON CONSUMPTION AND POPULATION DENSITY CHANGES OF DOMINANT PLANKTONIC DIATOMS IN LAKE CONSTANCE,
Konstanz Univ. (Germany, F.R.). Limnological Inst.
U. Sommer, and H.-H. Stabel.
Journal of Ecology, Vol. 71, p 119-130, March, 1983. 4 Fig, 2 Tab, 20 Ref.

Descriptors: *Silicon, *Diatoms, Lake Constance, Seasonal variation, Population density, Succession.

Interactions between silicon concentration and diatom growth have been studied in Lake Constance with data on number and volume of cells per unit volume of water and concentration of dissolved reactive silicon. Concentration of dissolved reactive silicon was found to decrease markedly during the spring and summer growth period of diatoms in 1979 and 1980. Amounts of silicon taken up per cell and per unit cell volume have been calculated from the changes in silicon concentration and the increases in population density for several diatom species. The silicon to cell quotient (mg per million cells) varied over a wide range from 0.005 for Stephanodiscus hantzschii to 0.72 for Synedra acus, while that of silicon per unit cell volume (mg/cu mm) varied over a narrower range from 0.10 for Stephanodiscus hantzschii and Fragilaria crotonesis to 0.36 for Synedra acus. A four-compartment model, that allows estimates of the rates of growth and of loss of diatom populations to be calculated, is outlined. Summer succession from Asterionella formosa to either Fragilaria crotonensis (in 1979) or Stephanodiscus binderanus (in 1980) is explained by interspecific differences in the effects of silicon concentration on growth and death. For Asterionella formosa, silicon depletion did not stop cell-division but led to the death of most of the population. For Fragilaria crotonensis and Stephanodiscus binderanus cell division stopped but cells did not die and population growth continued after the concentration of dissolved silicon had increased again. EFFECTS OF ORGANIC MATTER ADDITIONS TO SEDIMENT ON THE GROWTH OF AQUATIC PLANTS,
Army Engineer Waterways Experiment Station, Vicksburg, MS. Environmental Lab.
J. W. Barko, and R. M. Smart.
Journal of Ecology, Vol. 71, No. 1, p 161-175, March, 1983. 6 Fig, 6 Tab, 68 Ref.

Descriptors: *Aquatic plants, *Organic matter, *Sediments, Submerged plants, Emergent plants, Growth, Nutrients, Organic carbon, Decomposing organic matter.

Growth of three completely submerged species (Elodea canadensis, Hydrilla verticillata, and Myriophyllum spicatum) and three partly emergent species (Myriophyllum aquaticum, Potamogeton nodosus and Sagittaria latifolia) was examined on a control sediment and on the same sediment to which different types of plant organic matter (two labile and three refractory) had been added. With the addition of 5% organic matter, growth varied with the nature of the addition and the species of plant. Growth of emergent species was generally less inhibited than that of submerged species on sediment receiving this low level of addition. With greater additions of organic matter, growth of both H. verticillata and P. nodosus was severely inhibited irrespective of the nature of the addition. Labile organic matter (5% addition) inhibited growth of H. verticillata to a decreasing extent with time. In contrast, sediments receiving a 5% addition of refractory organic matter remained inhibitory to this species for at least 14 weeks. Growth was unrelated to concentration of Fe, Mn or PO4 in the interstitial water of sediments. However, low concentration of N in both interstitial water and plant shoots suggested possible N limitation of growth on sediment receiving refractory organic matter. Growth of H. verticillata on sediment with refractory organic matter added in a separate experiment was, however, unaffected by N addition to either the sediment, or water, or both. Growth of all species was negatively correlated with mean dissolved organic carbon (DOC) concentration in the interstitial water of the sediments. Growth inhibition may have resulted from the accumulation of toxic, soluble organic carbon compounds during anaerobic decomposition. The lesser inhibition of emergent plants compared with the submerged plants may have been due to the greater rhizosphere-oxidixing abilities of the former. The possible role of organic accretion in sediments was considered in relation to patterns of aquatic plant distribution and succession. (Author's abstract)

PHYTOPLANKTON PRODUCTION AND WINTER MIXING: CONTRASTING EFFECTS IN TWO OLIGOTROPHIC LAKES,
Department of Scientific and Industrial Research, Taupo (New Zealand). Ecology Div.
W. F. Vincent.
Journal of Ecology, Vol. 71, No. 1, p 1-20, March, 1983. 8 Fig, 9 Tab, 34 Ref.

Descriptors: *Mixing, *Phytoplankton, *Productivity, Seasonal variability, Thermal stratification, Light, Biomass, Photosynthesis, Nutrients, Limnology, Oligotrophic lakes, Storms, Nitrogen, Phosphorus, New Zealand.

Two deep oligotrophic lakes in the center of North Island, New Zealand, shared several limnological features but differed in their seasonal patterns of algal production. Lake Waikaremoana followed, in its thermal stratification, the classic pattern for temperate warm-monomictic lakes. During winter circulation, light availability to the phytoplankton was reduced by a factor of at least 13 relative to that in spring and summer, and there was no increase supply of phosphorus, which later controlled the amount of growth of its phytoplankton. Concentrations of algal biomass and algal production rates were predictably low, but rose rapidly with increased irradiance in spring. Lake Taupo experienced similar thermal stratification and mixing, but concentrations of algal biomass and algal photosynthetic production rose to maxima for the year during winter isothermy when temperatures were at their annual minimum and when mixing extended to the bottom of the lake. Winter circulation brought an increased supply of phosphorus and, more importantly, nitrogen which later controlled the amount of algal growth in the euphotic zone. This increased availability of potentially limiting nutrients offset the effects of low light availability and low temperature. Lake Taupo, and other nearby lakes which behave similarly, form intermediates between temperate lakes with typical winter minima of algal production and many tropical lakes which experience maximum phytoplankton production during storm-induced mixing. ON THE ENVIRONMENTAL ISOTOPE METHOD FOR DETERMINING THE WATER BALANCE COMPONENTS OF SOME LAKES,
Institute of Physics and Nuclear Techniques, Krakow (Poland).
A. Zuber.
Journal of Hydrology, Vol. 61, No. 4, p 409-427, March, 1983. 6 Fig, 1 Tab, 23 Ref.

Descriptors: *Hydrologic budget, *Isotope studies, *Lakes, Isotopic tracers, Oxygen isotopes, Deuterium, Lake evaporation.

The paper deals with the isotope balance method applied to lakes, which can be assumed as being under steady-state conditions. It is shown that the long-term averages and non-normalized temperatures can be used in the balance equations. The applicability of the proposed approach was tested by the interpretation or reinterpretation of several

known case studies (Chala, Titicaca, Waid, Burdur, Beysehir and Egridir lakes). An isotope study of a small artificial lake (1,200,000 cu m) is presented and compared with whole-body tracing by K3(60)Co(CN)6. This artificial tracer does not appear useful for long-term tracing of surface waters. The water balance equation for each of the lakes considered was solved with the aid of the isotope balance equation of O18. Applying the calculated components of the water balance, the isotope balance equation of deuterium was solved for finding the values of kinetic enrichment for deuterium. These values, which give the fit of the evaporation lines to the experimental data, do not agree with the values known from direct laboratory experiments, thus they have to be treated as apparent values, which may be useful for future field work. OBSERVATIONS OF TRANSPORT TO SURFACE WATERS FROM A PLUNGING INFLOW TO LAKE MEAD,
California Univ., Berkeley. Dept. of Civil Engineering.
H. B. Fischer, and R. D. Smith.
Limnology and Oceanography, Vol. 28, No. 2, p 258-272, 1983. 13 Fig, 6 Ref.

Descriptors: *Lake Mead, *Plunging inflow, *Mixing, Nutrients, Salinity, Wave action, Internal waves, Thermocline, Algal growth, Hydrodynamics, Seiches, Water temperature, Water circulation.

Algae growing in the surface water of Las Vegas Bay, an arm of Lake Mead, may receive nutrients contained in the stream entering through Las Vegas Wash. The stream water is more dense than the lake water due to dissolved salts. Existing hydrodynamic theory predicts that the stream should form a submerged layer isolating the nutrients from the surface. The theory was tested by introducing dye into the stream during two 14-day experiments; salinity, temperature, and dye concentration were monitored in the inner portion of the bay. Significant dye concentrations were found in the surface waters during both experiments, and two modes of internal waves with amplitudes up to 6 m were observed. The wave motion provided the main mechanism for transport to the surface in the first experiment; in the second an additional mechanism was the creation and destruction of temporary thermoclines due to meteorological variation. An approximate nutrient balance shows that in each case about 10% of the entering nutrients were available to the surface water within the 14-day period of the experiments. (Author's abstract)

TEMPERATURE, HEAT, AND MIXING IN LAKE VALENCIA, VENEZUELA,
Colorado Univ. at Boulder. Dept. of Environmental, Population, and Organismic Biology.
W. M. Lewis, Jr.
Limnology and Oceanography, Vol. 28, No. 2, p 273-286, 1983. 5 Tab, 28 Ref. DEB7604300, DEB7805342, DEB8003883.

Descriptors: *Water temperature, *Mixing, Lake Valencia, Venezuela, Weather, Stratification, Water circulation, Heat budget, Eddy diffusion, Seasonal variation, Wind, Thermal stratification, Lake evaporation.

Water temperature profiles, weather data, and lake level data spanning a 2-yr period for Lake Valencia, Venezuela (10 degrees N, 67 degrees W), are used in an analysis of thermal regime, mixing, and heat flux. The lake, which has an area of 350 sq km and mean depth of 19 m, is warm monomictic; it becomes isothermal annually near the end of November, at the onset of the dry season. The water column during stratification consists of an upper mixed layer, which averages 13 m but varies greatly in thickness, followed by alternating thick layers of positive and negligible density gradients. The number of layers changes through time. Vertical eddy diffusivites during stratification vary from 0.23 cu cm/s at 20 m to 0.09 at 35 m. The mean annual heat budget is 5,308 cal/sq cm. Evaporative heat loss and net radiation flux are the two largest heat budget elements; net back radiation and sensible heat loss are important secondary terms. Seasonality, is principally traceable to heat budget terms influenced by minimum air temperature, whereas week-to-week variation is influenced by other terms as well. Maximum stability of the water column is about 350 g-cm/sq cm with little variation between yr. Work of the wind in distributing heat is 2,630 g-cm/sq cm for 1977 and 3,156 in 1978. Stability responds in a significant way to weather changes, even during stratification. (Author's abstract)

THE CHEMICAL COMPOSITION OF LAKES IN THE NORTH-CENTRAL UNITED STATES,
Minnesota Univ., Minneapolis. Dept. of Agriculture and Applied Economics.
E. Gorham, W. E. Dean, and J. E. Sanger.
Limnology and Oceanography, Vol. 28, No. 2, p 287-391, 1983. 11 Fig, 1 Tab, 43 Ref. GS23309, GB2448, GB6018, GB18800.

Descriptors: *Lakes, *Specific conductivity, *Ions, Water chemistry, Climates, Glacial drift, Limnology, Geology, Arid climates, Minerals.

Lake waters of the north-central U.S.A. are classified into five groups, based on increasing specific conductivity and changes in ionic composition from east to west, from Wisconsin through Minnesota to North and South Dakota. The most dilute group of waters has specific conductivities <29 micro mhos/cm at 25 C; the most concentrated group has specific conductances that range from 7,000 to 73,000 micro mhos. As conductivity increases all major ions increase, but there is a shift in cation dominance from Ca(2+) to Mg(2+) to Na(+), and in anion dominance from HCO3(-) to SO4(2-). This shift partly reflects a westward increase in climatic aridity, and partly a westward sequence of glacial drifts from noncalcareous to calcareous and thence to calcareous with abundant sulfur-bearing minerals. Levels of pH, K, Cl, F, B, and SiO2 also show a distinct westward increase. Concentrations of NO3(-) and Mn increase from east to west, but the trend is less distinct. Concentrations of Fe vary widely without any trend over the range of conductivity. Color, mostly from dissolved organic matter, is controlled chiefly by lake depth, except for lakes with extensive peatlands in their drainage basins. (Author's abstract)

Descriptors: *Eutrophication, *Phytoplankton, *Organic matter, Eutrophic lakes, Particulate matter, Bacterial, Detritus, Japan.

The rapid increase of phytoplankton biomass was the major process for the increase of particulate organic matter in Lake Kasumigaura in 1980. During the first phytoplankton pulse in the bloom relative abundance of each component of organic matter in the lake water was: dissolved organic matter 100, phytoplankton 28, bacteria 27, and detrital particle 27. This relative abundance was maintained as a steady-state oscillation throughout the spring bloom similar to that usually observed in moderately eutrophic waters. Thus phytoplankton abundance in the standing stock of organic matter of the hypereutrophic water during the spring bloom does not show any marked difference from that of moderately eutrophic waters. f regionally plentiful coal and oil shale n the western United States may result ease of atmospheric emissions in and northwestern Colorado, as may smelt- increase in population. Such emissions previously associated with water quality n from acid rain. Lakes of the Flat Tops Area in northwestern Colorado are acidification if precipitation in the area s acidic as that of the northeastern tes. About 50% of the titration alkalinity t poorly buffered lakes is from dilution nt acid rather than neutralization. Alka- adily predicted from watershed charac- cluding lake altitude, fraction of exposed nd drainage area. Alkalinity values as micro eq/l occur in the higher-altitude he basis of alkalinity titration curves for tudied, an alkalinity of 200 micro eq/l or necessary to adequately protect a lake ipitation as acidic as that of the north- nited States. Most lakes at altitudes of greater are predicted to have alkalinity 200 micro eq/l or less. About 370 lakes total surface area of about 157 ha are to be sensitive to acidification. (Moore-

AL LIMNOLOGICAL CHANGE AND LANKTON PRODUCTION IN OHA- HYDRO-ELECTRIC LAKE ON THE O RIVER,
Department of Scientific and Industrial Research, Taupo (New Zealand). Div. of Marine and Freshwater Sciences.
G. W. Coulter, J. Davies, and S. Pickmere.
New Zealand Journal of Marine and Freshwater Research, Vol. 17, No. 2, p 169-183, June, 1983. 8 Fig, 4 Tab, 35 Ref.

Descriptors: *Limnology, *Phytoplankton, Nutrients, Chlorophyll a, Seasonal variation, Flow rate, Water temperature, Stratification, Biomass, Nitrates, Phosphorus, Hydroelectric power, Reservoir operation, Environmental effects, Primary productivity, Lake Ohakuri.

The Waikato River originates in oligotrophic Lake Taupo, but becomes chemically enriched before reaching Lake Ohakuri, where phytoplankton increases dramatically. Data were collected over 2 years, including daily measurement for 1 year of N, P, Si, and chlorophyll a in water leaving the lake. The hypolimnion remained stagnant in summer, and inorganic-N peaked after lake overturn. NO3-N showed a marked seasonal cycle in concentration and total flux in water leaving the lake, which may not correspond with input rates from the catchment. Melosira granulata var. angustissima dominated the phytoplankton in summer, and Chlamydomonas spp. and Cyclotella spp. in winter. In summer, weekly cycles in algal abundance, which correlated inversely with NO3-N and DRP (dissolved reactive phosphorus) concentrations, were dictated by weekly flow cycles resulting from the requirements of hydro-electric power generation. Flow rate and temperature appear the dominant factors regulating phytoplankton abundance. Shorter residence time and probably slower growth rates in winter, and longer residence and more rapid growth in summer interact critically. Phytoplankton production in river lakes such as Ohakuri with a brief water residence time is more appropriately represented by the mass flow of algal material through it than by the abundance of the standing stock. Summer phytoplankton biomass in Lake Ohakuri is equivalent only to a mildly eutrophic condition, but the amount generated and then lost from the lake is equivalent to production in a lake of much higher trophic status in a closed basin. RESPONSE OF PLANKTONIC ROTIFERS TO THE EUTROPHICATION PROCESS AND TO THE AUTUMNAL SHIFT OF BLOOMS IN LAKE BIWA, JAPAN. I. CHANGES IN ABUNDANCE AND COMPOSITION OF ROTIFERS,
Polish Academy of Sciences, Warsaw. Inst. of Ecology.
A. Hillbricht-Ilkowska.
Japanese Journal of Limnology, Vol. 44, No. 2, p 93-106, April, 1983. 5 Fig, 6 Tab, 21 Ref.

Descriptors: *Eutrophication, *Rotifers, Lake Biwa, Plankton, Seasonal variation, Diatoms, Chlorophyta, Water temperature, Foods.

The density of planktonic rotifers in Lake Biwa was 100-3,000/l from September to December, 1980. This level is remarkably higher than that previously reported by Yamamoto, who noted no more than 10-600/l, although the northern basin (LBN) has been, in general, regarded as having lower values than the southern basin (LBS). An increase in population density was observed in the following species: small and fine particle feeders like Keratella cochlearis, Collotheca pelagica, Brachionus species group and K. quadrata; and grasspers such as Polyarthra vulgaris and P. dolichoptera. The long-term changes may well be evidence for the accelerated eutrophication of Lake Biwa. The actual trophic difference between both basins in reflected in 1) greater abundance of rotifers (maximum of 3,000/l); 2) greater contribution of K. cochlearis (especially f. tecta = 50%); and 3) higher Trophic State Index (TSI = 75) in the LBS; on the contrary, corresponding values were 300/l, K. cochlearis f. tecta = 1% and TSI = 46, respectively, in the LBN. During the autumnal shift of the blooms from green algae to diatoms coupled with the autumnal cooling of the water there was a succession of dominant species with food selection of different size particles: K. cochlearis, Polyarthra spp., K. quadrata. In November, a considerable increase in the number of K. cochlearis f. tecta was recognized. (Author's abstract)

RESPONSE OF PLANKTONIC ROTIFERS TO THE EUTROPHICATION PROCESS AND TO THE AUTUMNAL SHIFT OF BLOOMS IN LAKE BIWA, JAPAN. II. CHANGES IN FECUNDITY AND TURNOVER TIME OF THE DOMINANT SPECIES,
Polish Academy of Sciences, Warsaw. Inst. of Ecology.
A. Hillbricht-Ilkowska.
Japanese Journal of Limnology, Vol. 44, No. 2, p 107-115, April, 1983. 1 Fig, 5 Tab, 12 Ref.

Descriptors: *Rotifers, *Eutrophication, Lake Biwa, Seasonal variation, Reproduction, Water temperature, Plankton, Foods, Detritus, Algae.

The egg-female ratio, i.e. the ratio of the numbers of amictic eggs to the number of females was analyzed for the dominant species, Keratella cochlearis, K. quadrata and Polyarthra vulgaris together with P. dolichoptera from September to December 1980 at six stations in the southern part of Lake Biwa. Irrespective of the decrease in water temperature from about 26 C in September to about 6 C in December, there was a considerable increase in the fecundity of these species in November. It was probably the effect of the temporal improvement of the food conditions, i.e., the increased detritus particles and nanoplanktonic algae. The birth rates were calculated as well as the tentative number of parthenogenetic generations for each sampling interval and for the whole sampling period; it ranged from 15 to 29 generations for K. cochlearis, 12-30 for P. dolichoptera and P. vulgaris, and 2-12 for K. quadrata, varying for each stations. IMPACT ON DAPHNIA PULEX OF PREDATION BY YOUNG YELLOW PERCH IN ONEIDA LAKE, NEW YORK,
E. L. Mills, and J. L. Forney.
Transactions of the American Fisheries Society, Vol. 112, No. 2A, p 154-161, March, 1983. 2 Fig, 2 Tab, 26 Ref. F-17-R.

Descriptors: *Predation, Population dynamics, Daphnia, Perch, Biomass, Fish food organisms, Oneida Lake, New York.

The response of a Daphnia pulex population to fluctuations in abundance of young (age-0) yellow perch Perca flavescens was examined in Oneida Lake, New York, 1975-1979. Comparisons of yellow perch biomass and D. pulex abundance suggested daphnid populations could tolerate predation by 10 kg of young fish/hectare but reproduction could not compensate for predation when biomass of young exceeded 20-40 kg/hectare. Consumption by young yellow perch exceeded D. pulex production in 1975 and 1977, when daphnids disappeared, but maximum daily consumption was less than 27% of production in 1976 when daphnids were abundant through late summer. Since 1968, D. pulex populations have persisted through late summer in years when young yellow perch were scarce and disappeared when young were abundant. The decisive role of young yellow perch in the regulation of D. pulex abundance is of importance to the broader fish community in Oneida Lake. (Author's abstract)

Group 2I—Water In Plants

EFFECT OF WATER-TABLE DEPTH ON SHOOT GROWTH, ROOT GROWTH, AND NODULATION OF MYRICA GALE SEEDLINGS,
Harvard Univ., Petersham, MA. Harvard Forest.
C. R. Schwintzer, and S. A. Lancelle.
Journal of Ecology, Vol. 71, No. 2, p 489-501, July, 1983. 5 Fig, 2 Tab, 31 Ref. DE777-02249.

Descriptors: *Water table gradient, *Growth, Peat soils, Sand, Soil types, Nitrogen fixation, Biomass, Root development, Oxygen uptake, Phenology.

Seedlings of Myrica gale, an actinorhizal dinitrogen-fixing shrub, were grown in two boxes with a gradient of water-table depth from 3-79 cm. The boxes were outdoors but sheltered from rain by translucent roofs. One box was filled with sand and the other with peat. The seedlings were harvested in autumn shortly before leaf-fall. The plants produced maximum biomass at water-table depths between 10 cm and 35 cm on both substrata but the total amounts produced were substantially greater on peat than on sand. Shoot-root quotients decreased with increasing water-table depth on both substrata but were much larger on sand. The roots did not penetrate below the water table and the orientation of the major lateral roots changed from primarily horizontal to semi-vertical with increasing water-table depth. Nodules formed 6-7% of the total seedling biomass in the wettest soils and decreased to 1% in the driest. Nodule roots showed maximum development in the wettest soils where they were relatively long and thick, and emerged through the surface into the air above. This is consistent with a functional role in enhancing nodule oxygen uptake under oxygen-limiting conditions. The considerable phenotypic plasticity in response to moisture and aeration exhibited by M. gale appears to be a valuable adaption in its natural habitat where the water level often fluctuates. SOME RELATIONSHIPS BETWEEN ENVIRONMENTAL RELIABILITY AND SEED DORMANCY IN DESERT ANNUAL PLANTS,
New Mexico State Univ., Las Cruces. Dept. of Biology.
K. E. Freas, and P. R. Kemp.
Journal of Ecology, Vol. 71, No. 1, p 211-217, March, 1983. 1 Fig, 1 Tab, 20 Ref.

Descriptors: *Desert plants, *Rainfall, Germination, Seasonal variation, Model studies, Seeds, Water controlled dormancy, Ecology.

There are two groups of annual species that grow in the northern Chihuahuan Desert of North America. Plants in one group germinate and complete their life cycle in late summer. Those in the other germinate in winter or early spring and complete their life cycle in the spring. The late summer season is characterized by abundant and reliable rain, while the winter-spring season has less abundant and less reliable rain. Several theoretical models have been suggested which predict that annual plants from uncertain environments may or may not have evolved innate dormancy to offset the possibility of population extinction due to complete germination followed by complete mortality under severely unfavorable conditions. These models were tested with a comparative experiment examining the germination responses of seeds collected from an annual species which grows during the more reliable summer season and two annual species which grow during the less reliable winter-spring season. The summer annual species does not have a genetically fixed innate dormancy, but the two winter annual species apparently have evolved a genetically controlled innate dormancy. All three annual species exhibited environmentally-controlled seed dormancy with respect to amount of rainfall. Seeds germinated only when the equivalent of more than 10 mm of rain fell. Above 15 mm of simulated rain, germination was positively correlated with increasing amount of rain in all three species. The importance of innate dormancy, water-controlled dormancy, and seed dispersal to the long-term survival of these species is discussed. (Author's abstract)

DISCRIMINATION OF GROWTH AND WATER STRESS IN WHEAT BY VARIOUS VEGETATION INDICES THROUGH CLEAR AND TURBID ATMOSPHERES,
Agricultural Research Service, Phoenix, AZ. Water Conservation Lab.
R. D. Jackson, P. N. Slater, and P. J. Pinter, Jr.
Remote Sensing of Environment, Vol. 13, No. 3, p 187-208, July, 1983. 19 Fig, 2 Tab, 17 Ref. 12-14-5001-38.

Descriptors: *Remote sensing, *Reflectance, *Water stress, Wheat, Drought, Satellite technology, Optical properties, Vegetation, Simulation.

Reflectance data were obtained over a drought-stressed and a well-watered wheat plot with a hand-held radiometer having bands similar to the MSS bands of the Landsat satellites. Data for 48 clear days were interpolated to yield reflectance values for each day of the growing season, from planting until harvest. With an atmospheric path radiance model and Landsat 2 calibration data, the reflectances were used to simulate Landsat digital counts (not quantized) for the four Landsat bands for each day of the growing season, through a clear (= 100-km meteorological range) and a turbid (= 10-km meteorological range) atmosphere. Several ratios and linear combinations of bands were calculated using the simulated data, then assessed for their relative ability to discriminate vegetative growth and plant stress through the two atmospheres. The results showed that water stress was not detected by any of the indices until after growth was retarded, and the sensitivity of the various indices to vegetation depended on plant growth stage and atmospheric path radiance. (Author's abstract)

THE INFLUENCE OF SNOW ON GROWTH AND SURVIVAL OF PLANTED TREES,
Eidgenoessisches Inst. fuer Schnee- und Lawinenforschung, Davos (Switzerland).
W. Frey.
Arctic and Alpine Research, Vol. 15, No. 2, p 241-251, May, 1983. 10 Fig, 5 Tab, 37 Ref.

Descriptors: *Snow cover, *Trees, Plant water potentials, Water stress, Seedlings, Subalpine zone, Dessication, Flushing.

In the subalpine zone at Davos, Switzerland, a trial plot of seven tree species was kept artificially snow free during two winter periods and compared with an equivalent trial plot under natural snow cover. Periodic measurements of water potential and water content showed that, during the winter period, there is a higher water stress in the snow free plants, especially Norway spruce (Picea abies (L.) Karst), and deciduous species, including European larch (Larix decidua Mill.). Seedlings of these species showed serious desiccation and an increased mortality compared with the snow-covered seedlings. Desiccation occurred predominantly on the parts of the snow-free seedlings that were exposed to the sun. Flushing in spring was retarded in the snow-free plot. All measured growth parameters showed more favorable results in the snow-covered plot. Sufficient snow cover is therefore a very important factor for the success of young seedlings in the subalpine zone, especially for Norway spruce, European larch, and deciduous broadleaf species. Descriptors: *Sediment distribution, *Shoals, *Scour, *Water depth, Navigation channels, Harbors, Estuaries, Rivers, Dredging, Bathymetry, *Florida, Mill Cove, St. Johns River.

It is often necessary to quantify changes i
depth brought about by either sedimenta
scour in enclosed or semi-enclosed water
Historical sedimentation patterns can be
estimate future patterns and then used to de
future dredging requirements for river, harb
estuary navigation channels. Comparison
area vs. depth curves provides a method fo
mining the depths in which sedimentati
scour are occurring. The area between tw
curves divided by the time difference betw
two surveys for which the curves are cons
will give the shoaling or scour rate. Shoa
scour rates can be determined as a func
water depth simply by taking the differer
tween the ordinates of the two curves divi
the time between the two surveys for any
water depth. This analysis can provide insig
sedimentation trends for enclosed for se
closed water bodies that routine plots of bat
ric changes cannot. Mill Cove, a semi-en
basin adjacent to the St. Johns River in Flo
used as an example. (Moore-IVI)

flows, *Ice cover, Free surfaces, Fall velo
Shear velocity, Roughness coefficient, Mathe
ical models.

The vertical distribution of the suspended sedi
in two-dimensional, uniform, and fully devel
turbulent flows under ice cover is formulated
the results of the kappa-epsilon turbulence m
of Launder and Spalding. Three sets of distribu
curves each corresponding to a particular valu
the ratio between the ice cover roughness and
roughness are presented in a form similar to
distribution curves of H. Rouse (Trans. ASCE
463, 1937) for free-surface flows. For the s
value of the ratio between the shear velocity
the fall velocity of sediment particles, the rel
concentration is less in ice-covered flows tha
free-surface flows. Under similar conditions,
relative concentration of suspended sediment
creases as the ratio of the ice cover roughnes
bed roughness increases. The agreement betw
the present formulation and the measurem
found in the literature is favorable. (Author's

TER MATRIC POTENTIAL EFFECTS REGATE STABILITY,
ricultural and Home Economics Experi- ion, Ames.
ncis, and R. M. Cruse.
ce Society of America Journal, Vol. 47, 78-581, May-June, 1983. 1 Fig, 2 Tab, 14

rs: *Soil water, *Soil aggregates, Soil ent, Soil erosion, Rain, Manure, Crop n, Aggregate stability.

t of soil water matric potential (psi m) is idered with most techniques utilized to aggregate stability. Rather, aggregate sta- ally is measured at psi m of 0 Pa or at an psi m. The objective of this study was to e psi m effects, in the range of 0 to -3,000 ability of natural soil aggregates obtained from a fencerow and from plots having a range of management histories. Aggregate stability, considered inversely related to the mass of soil detached by impact of falling water drops, increase markedly as psi m decreased from 0 to -500 Pa. Similar psi m changes at psi m $<$ -500 Pa had smaller effects on aggregate stability. Significant differences in stability of aggregates obtained from plots with different cropping and/or manuring histories, were sometimes undetectable at psi m $<$ -500 Pa but were more consistently detected at psi m = Pa. Data from this study indicate that aggregate stability is very sensitive to psi m particularly at psi m near zero. Techniques for comparing aggregate stability between soils or soil treatments should ensure equal values of psi m exist for all aggregates. Measurements made over a range of psi m should yield better comparisons of aggregate stability between soils than measurements made at one psi m. (Author's abstract)

SEMI-EMPIRICAL CORRELATIONS FOR FINE AND COARSE COHESIONLESS SEDIMENT TRANSPORT,
Lamar Univ., Beaumont, TX.
P. A. Mantz.
Proceedings of the Institution of Civil Engineers, Vol. 75, p 1-33, 1983. 6 Fig, 13 Tab, 28 Ref.

Descriptors: *Sediment transport, *Hydraulic resistance, *Bedform development, Bed load, Suspension, Suspended load, Flow velocity, Flow depth.

A total of 54 laboratory experiments were conducted with fine, cohesionless, silica sediment under water flow. The equilibrium sediment transport, bedform development and hydraulic resistance for three grades of almost equal-sized silica solids (of median diameter 0.018 mm, 0.042 mm and 0.123 mm) were investigated for three conditions of flow depth (0.03 m, 0.06 m and 0.12 m) and for six conditions of average flow velocity (from 0.2 to 0.7 m/s at increments of 0.1 m/s). Experiments were conducted in a 10 m long and 0.30 m wide recirculating, tilting, laboratory flume which contained direct town supply, softened water. The water chemistry was controlled so that the sediment behaved as if cohesionless, and the water temperature was allowed to reach an equilibrium maximum of about 25 C. The sediment transport was analysed according to the streampower theory developed by Bagnold. The theory was extended for these shallow flows, and it was assumed that the rate of applied flow energy was dissipated partly by the friction and moving bed load solids, partly by the turbulence associated with bedforms, partly by the gravitational settling of suspended load solids, and partly by the friction of the unimpeded flow. Unique correlations were subsequently derived for the work rates associated with the moving bed load or suspended load, and the streampower excess which excluded that necessary for incipient transport or incipient suspension. An analysis of readily available field data was made for comparison with the laboratory data. Bed load data were abstracted from a recent collation by Bagnold. The data covered a coarse-grain diameter range from 0.3 mm to 300 mm, and a large flow-depth range from 0.10 m to 12 m. Suspended load data were abstracted from river data monitored and collated by the US Geological Survey. They included both shallow and deep rivers (ranging from 0.2 m to 9 m in depth) from the States of Alaska, New Mexico and Arizona. (Author's abstract)

AN APPLICATION OF OPERATIONS RESEARCH METHODS TO BEACH RENOURISHMENT PROJECTS,
University of South Florida, Tampa.
E. W. Shows.
Water Resources Bulletin, Vol. 19, No. 2, p 249-253, April, 1983. 1 Tab, 6 Ref.

Descriptors: *Beach erosion, *Mathematical models, *Surveys, Florida, Erosion control, Capital costs, Recreation, Economic feasibility.

Mathematical models have been widely used in business to minimize cost and maximize profit. In this paper such models are used to help determine the optimum strategy for a beach renourishment project including the initial and subsequent fill quantities and the length of a complete renourishment cycle. The importance of considering economic factors is emphasized, and the sensitivity of the optimal values to changes in the basic parameters of the models are discussed. The possible extensions and limitations of the models are considered. (Author's abstract)

CONFLUENCE SCOUR IN COARSE BRAIDED STREAMS,
Alberta Univ., Edmonton. Dept. of Geography.
P. Ashmore, and G. Parker.
Water Resources Research, Vol. 19, No. 2, p 392-402, April, 1983. 10 Fig, 3 Tab, 35 Ref.

Descriptors: *Scour, *Braided streams, Abrasion, Erosion, Model studies, Confluent streams, Reynolds numbers, Sand.

Laboratory modeling was performed of confluence scour in coarse braided streams and the results were compared with field data using an appropriate scaling law. The major controls of scour depth are isolated and may be used for design predictions. The findings suggest that confluence scour in gravel braided streams can be modeled reasonably well in coarse, noncohesive bed material. Scale effects, presumably resulting from low model Reynolds numbers, are not greater than about 10%. Generally speaking, the angle of confluence is the major influence on scour depth, but the relationship is modified slightly by the relative discharge of the two channels when this difference becomes large. If one channel approaches twice the size of the other, the relationship with the angle of confluence becomes poor. For angles between 30 and 90 degrees, the relationship is almost linear. Maximum relative scour depth rarely exceeds 6.0. This relationship covers the most common naturally occurring confluence angles. The influence of bed material sorting and cohesiveness is apparent in comparing data sets from different sources. Cohesive bed material gives markedly lower depths than noncohesive material, while poorly sorted sand may give slightly lower depths than well sorted sand of the same mean size. Coarse lag material is absent from the scour holes even in poorly sorted sand. Confluence scour depth is clearly independent of valley parameters for the range of measurements reported. However, there is no reason to believe that the same scour relation should apply to such cases as large, low-slope sand bed braided streams. (Baker-IVI)

DENSITIES OF WET AGGREGATED SEDIMENT FROM DIFFERENT TEXTURED SOILS,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
F. E. Rhoton, L. D. Meyer, and F. D. Whisler.
Soil Science Society of America Journal, Vol. 27, No. 3, p 576-578, May-June, 1983. 1 Fig, 2 Tab, 8 Ref.

Descriptors: *Sediment transport, *Soil density, *Soil aggregates, Soil texture, Sediment density, Rain, Deposition, Interstitial water.

The density of wet aggregated sediment is a major factor controlling its fluvial transport and deposition. Since this property varies depending on the volume of aggregate pores filled with water, the use of dry aggregate densities in sediment transport studies may result in significant underestimations of wet sediment densities and consequently overestimations of transport distances. Therefore, this study was conducted to measure the densities of wet aggregates that exist during fluvial transport of sediment from agricultural soils. Samples from six soils, ranging in texture from silty clay to sandy loam, were wetted and agitated to simulate the stresses of raindrop impact. Two size ranges (1.00 to 0.50, and 0.50 to 0.25 mm) were collected from this sediment by wet sieving, then drained at a suction of 50 cm of water and weighed. The sedi-

ment volume was measured to the nearest 0.05 mL in a displacement vessel. Wet aggregate densities approximated 2.0 Mg/cu m and varied little among soils, or between the two size ranges. No variations in aggregate density could be directly attributed to differences in aggregate textures. (Author's abstract)

MULTIELEMENTAL AND HYDROCHEMICAL STUDY OF HOLY ZAMZAM WATER,
A. Naeem, M. Y. Alsanussi, and A. A. Almohandis.
Journal of the New England Water Works Association, Vol. 97, No. 2, p 158-169, June, 1983. 3 Fig, 3 Tab, 6 Ref.

Descriptors: *Well water, *Saudi Arabia, *Water chemistry, Drinking water, Heavy metals, Minerals, *Water analysis.

A water sample from the Zamzam Well, located in the holy city of Makkah in the Western Province of the Kingdom of Saudi Arabia, was analyzed with the help of neutron activation, inductivity coupled plasma and classical techniques. Multielement composition, the hydro-chemical properties, and the potability of the water from a chemical viewpoint are reported. A total of 34 elements have been found with calcium (Ca), magnesium (Mg), sodium (Na), and chloride (Cl) in the highest concentrations. The elements Sb, Be, Bi, Br, Co, I, Mo are < 0.01 ppm. Only traces of Cr, Mn, and Ti have been found in Zamzam water. Hydrochemical study of Zamzam water indicates that it is a sodium chloride water and of meteoritic origin. The four toxic elements arsenic (As), cadmium (Cd), lead (Pb), and selenium (Se) have been found below the danger level of human consumption. Chemically Zamzam water is suitable for drinking purposes. (Author's abstract)

INOSITOL-PHOSPHATES; HYDROLYSIS, STABILITY AND ANALYSIS,
Technische Hogeschool Twente, Enschede (Netherlands). Dept. of Chemical Technology.
W. Potman, and L. Lijklema.
Water Research, Vol. 17, No. 4, p 411-414, April, 1983. 4 Fig, 1 Tab, 16 Ref.

Descriptors: *Phosphates, *Bottom sediments, *Hydrolysis, Electrophoresis, Hydrogen ion concentration, Cycling nutrients, Detritus.

Inositol-phosphates are a class of phosphate-rich compounds occuring in sediments and aquatic systems. Their extraction from sediments and plant material and subsequent separation should be performed under conditions where these compounds are stable, whereas quantitative estimation of the individual components requires complete hydrolysis but without degradation of the inositol formed. The study showed that chemical hydrolysis can be performed at a low pH and 100 C. Extractions should be performed by preference in alkaline solutions at moderate temperatures. (Author's abstract)

TRANSLOCATION OF INORGANIC/ORGANIC MERCURY IN A MODEL AQUATIC SYSTEM,
Hyogo Prefecture Public Health Inst., Kobe (Japan).
J. Yamamoto, Y. Kaneda, Y. Hikasa, and E. Takabatake.
Water Research, Vol. 17, No. 4, p 435-440, April, 1983. 5 Fig, 4 Tab, 18 Ref.

Descriptors: *Organomercury compounds, *Bottom sediments, Spectrophotometry, Path of pollutants, Translocation, Model studies.

The volatile organic mercury at subnanogram level was determined by steam distillation Magos treatment and flameless atomic absorption spectrophotometry after preconcentration with silvered sand. By this technique, down to 0.1 ng of methyl mercury can be determined with good precision (+ or - 5%). Application of the technique to our aquatic model system made clear that much higher ratio of organic mercury (nearly 8%) to the total one was in water overlying organic sediment than the water sample overlying sandy sediment (approximately 3.5%). In natural water, therefore, it would seem that the content of organomercurials are less than 10% to that of total mercury. (Author's abstract)

OXYGEN ISOTYPE RATIOS IN GERMAN GROUNDWATER,
Kernforschungsanlage Juelich G.m.b.H. (Germany, F.R.). Inst. fuer Radioagronomie.
H. Forstel, and H. Hutzen.
Nature, Vol. 304, No. 18, p 614-616, August, 1983. 2 Fig, 2 Tab, 10 Ref.

Descriptors: *Oxygen isotopes, *Groundwater, Precipitation, Spatial distribution, Temperature, Altitude, Germany.

The natural variation in the O18/O16 ratio in precipitation has a characteristic global pattern, a continuous decrease from the Equator towards the polar regions, corresponding to the worldwide distribution of the local mean annual temperature. This global pattern is not, however, sensitive enough to predict the local O18/O16 ratio in precipitation. A survey of groundwater throughout the Federal Republic of Germany was obtained from about 900 samples of the municipal water supply. A multicorrelation study demonstrates that both distance from the coast and height above sea level determine the local O18/O16 ratio, and that this ratio generally decreases from the northern coast towards the southern mountainous region. The geographical variation in the O18/O16 ratio may serve as a basis for paleoclimatological, plant-physiological and food-analytical applications. (Moore-IVI)

CHEMICAL COMPOSITION OF NATU WATERS IN THE KINASA LANDSLIDE A
Nagoya Univ. (Japan). Water Research Inst.
Y. Kitano, and S. Nakamura.
Japanese Journal of Limnology, Vol. 44, No. 132-138, April, 1983. 5 Fig, 1 Tab, 10 Ref.

Descriptors: *Chemical composition, *Na waters, *Landslides, Kinasa, Snowmelt, Sulf Carbon dioxide, Carbonates, Groundwater.

Waters were collected in the Kinasa landslide to confirm whether the source of the waters only rain and snow melt water or if deep gro water was also present. Chloride concentra was very low and uniform. Therefore, the ch cal constituents in the waters are principally re ed to the dissolution from rocky materials thro chemical and weathering processes. Bicarbo and sulfate concentrations of the natural wa were high and varied. It is presumed that ro materials are weathered chemically by car dioxide underground. Calcium and magnesium were dissolved preferentially from the rocky m rial and carbon dioxide changes to bicarbo ions. At that time silicate minerals change into c minerals. The origin of carbon dioxide und ground is assumed to be in the volcanic activity the area. Calcium and magnesium concentration natural waters may well indicate the extent of chemical weathering of rocky materials in cont with the waters and also the extent of the for tion of clay minerals. Natural waters in landsl

tertiary rocks have been known to be sulfate concentration derived mostly e oxidation of iron sulfides. (Baker-IVI)

G WATER DISCHARGES INTO A SEA SLOPING BED,
Electricity Generating Board, Leather- ngland). Central Electricity Research

queen, and R. W. Preston.
search, Vol. 17, No. 4, p 389-395, April, g, 7 Ref.

s: *Cooling water, *Powerplants, pollution, *Tidal effects, Temperature Slopes.

l solutions for the rise in background peratures due to the discharge of cooling m a power station are developed. Previ- has taken account of the cooling water flow rate and temperature increase through the station, the tidal excursion and residual drift, cross-tide dispersion and heat exchange between the water and atmosphere in a sea with constant depth. The treatment in the present paper incorporates the slope of the sea bed. The mathematical feature of the analysis is that a closed form for the background (or far-field) temperature distribution is obtained in terms of confluent hypergeometric functions. The parameters which define these functions involve the site hydrographic feature and cooling water system parameters. Results are presented which indicate the sensitivity of the temperature rise to bed slope and the position of the discharge. The temperature at the shore, which may be an important ecological indicator and station design parameter, decreases as the distance of the outlet from the shore increases; the effect of the bed slope on the rate of decrease is quantified. GROWTH RESPONSE AND SPECTRAL CHARACTERISTICS OF A SHORT SPARTINA ALTERNIFLORA SALT MARSH IRRIGATED WITH FRESHWATER AND SEWAGE EFFLUENT,
Delaware Univ., Newark. Coll. of Marine Studies.
M. A. Hardisky, R. M. Smart, and V. Klemas.
Remote Sensing of Environment, Vol. 13, No. 1, p 57-67, March, 1983. 3 Tab, 1 Fig, 35 Ref.

Descriptors: *Spartina, *Salt marshes, *Remote sensing, Growth, Satellite technology, Biomass, Nitrogen, Spectral radiance, Salinity, Effluent, Vegetation, Optical properties, Radiance, Nutrients.

A short Spartina alterniflora salt marsh was irrigated with sewage effluent and freshwater. Vegetation response to nitrogen additions in the sewage effluent and soil salinity dilution by the freshwater was monitored spectrally with a GSFC MARK II hand held radiometer. The radiometer was spectrally configured to match bands 3, 4, and 5 of the Landsat-4 Thematic Mapper. Freshwater and sewage irrigations promoted live tissue production in the marsh until October. Control areas exhibited no net live biomass production after August. Radiance data expressed as the vegetation index and the infrared index were successfully correlated to increased live leaf biomass in the treated marsh. Significant correlations were found to exist between spectral radiance data and live leaf biomass, a live-dead leaf biomass ratio or percent live leaf biomass of the experimental areas. Successful spectral detection of biomass changes resulting from some perturbation suggests remote sensing as a viable tool for stress detection in S. alterniflora salt marshes. (Author's abstract)

CHESAPEAKE BAY: AN UNPRECEDENTED DECLINE IN SUBMERGED AQUATIC VEGETATION,
R. J. Orth, and K. A. Moore.
Science, Vol. 222, No. 4619, p 51-53, 7 October, 1983. 2 Fig, 21 Ref.

Descriptors: *Aquatic plants, *Submerged plants, *Chesapeake Bay, Estuarine.

Data on the distribution and abundance of submerged aquatic vegetation in Chesapeake Bay indicate a significant reduction in all species in all sections of the bay during the last 15 to 20 years. This decline is unprecedented in the bay's recent history. The reduction in one major species, Zostera marina, may be greater than the decline that occurred during the pandemic demise of the 1930's. The data used to determine the past and present distribution of bay grasses were acquired from recent aerial mapping studies, field surveys, biostratigraphical analyses of estuarine sediments for seeds and pollen of bay grasses, older archived photographs, and anecdotal information. The pattern of vegetation loss has not been uniform throughout the bay. The evidence of a major, regionally isolated change in the submerged grass communities over the last 20 years suggest that this estuarine system has been undergoing an environmental stress of major proportions. Although storms may have hastened the decline in certain sections of the bay, the overall pattern appears to be one of chronic decline that began in the upriver and upper bay areas and continues to the present. TIDAL AND LOW-FREQUENCY NET DISPLACEMENT IN A COASTAL LAGOON,
Harbor Branch Foundation, Inc., Fort Pierce, FL.
N. P. Smith.
Estuaries, Vol. 6, No. 3, p 180-189, September, 1983. 11 Fig, 16 Ref.

Descriptors: *Lagoons, *Tidal currents, Water currents, Flow, Flushing, Wind, Florida.

Four, 32-day current meter records from the Indian River lagoon, Florida, are used to characterize flow patterns along the Intracoastal Waterway in a coastal lagoon. The M2 tidal constituent amplitude decreases from 58 cm/s near the Fort Pierce Inlet to only 7 cm/s in the interior of the lagoon. The relative importance of the nontidal variance in the current meter records increases from 0.6% to 26.6% of the total over the same distance. Plots of net displacement over time intervals of one to 16 days suggest relatively rapid flushing near the inlet, but in the interior of the lagoon periods of little or no net movement are increasingly common. Low-frequency motions at all four sites are coherent with windstress over time scales in excess of approximately two days. (Author's abstract)

CIRCULATION CHANGES IN THE SHEEPSCOT RIVER ESTUARY, MAINE, FOLLOWING REMOVAL OF A CAUSEWAY,
Maine Univ. at Orono. Dept. of Botany and Plant Pathology.
B. J. McAlice, and G. B. Jaeger, Jr.
Estuaries, Vol. 6, No. 3, p 190-199, September, 1983. 5 Fig, 2 Tab, 16 Ref.

Descriptors: *Water circulation, *Estuaries, *Tidal currents, Salinity stratification, Gravitational circulation, Causeway, Maine.

A causeway which had restricted tidal flow in a portion of the Sheepscot River estuary was removed late in 1974. Flowmeter data from moored plankton nets fished over full tidal cycles, and salinity observations made in conjunction with the net sets, were used to evaluate the effects of causeway removal on circulation in the estuary. Tidal flows in the main channel increased by almost 50%. This increase was accompanied by substantial decreases in salinity stratification and in the strength of the gravitational circulation. PRODUCTIVITY, DETRITUS FLUX, AND NUTRIENT CYCLING IN A CAREX LYNGBYEI TIDAL MARSH,
British Columbia Univ., Vancouver. Westwater Research Centre.
R. U. Kistritz, K. J. Hall, and I. Yesaki.
Estuaries, Vol. 6, No. 3, p 227-236, September, 1983. 8 Fig, 34 Ref.

Descriptors: *Sedge, *Primary productivity, *Nutrient cycling, Detritus, Tidal marshes, Estuaries, Standing crop, Biomass, Nitrogen, Phosphorus, Leaching, Nutrients, Seasonal variation, British Columbia.

Net annual primary production of a sedge Carex lyngbyei dominated tidal marsh in the Fraser River estuary, British Columbia, Canada was 634 g ash-

free dry weight (AFDW) per sq m per yr (687 g dry weight per sq m per yr). Mean maximum shoot elongation during the short (May to August) growing season was 1.88 cm per day from overwintering shoots. The maximum above-ground standing crop of 690 g AFDW per sq m represented only 25% of the total below-ground biomass, which appears to be controlling most of the critical life history processes of the sedge marsh. An estimate of 14% of the aboveground standing crop was lost through leaching of dissolved organic carbon from the growing plant. Aboveground tissue losses, which were negligible during the growing season, occurred primarily via translocation in autumn and tidal export during the winter. In situ measurements showed that of the original maximum standing crop, approximately 38%, 37%, and 25% were lost by downward translocation, tidal export, and sediment burial, respectively. Based on changes in above and belowground nutrient pools, rapid spring (May to late June) uptake rates of 109 mg N per sq m per day and 23.0 mg P per sq m per day by shoots were followed by downward translocation rates of 44.8 mg N per sq m per day and 12.2 mg P per sq m per day during late June to the end of August. Aboveground leaching rates were estimated as 23.9 mg N per sq m per day and 7.8 mg P per sq m per day and belowground uptake rates as 100 mg N per sq m per day and 26 mg P per sq m per day; root uptake occurred primarily after late June. Nutrient levels in decomposing litter more than doubled over the winter period showing a pattern of nutrient enrichment characteristic of marsh ecosystems. (Author's abstract)

TIDAL AND SUBTIDAL WATER VOLUME EXCHANGE IN AN ESTUARINE SYSTEM,
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
E. M. Swenson, and W.-S. Chuang.
Estuarine, Coastal and Shelf Science, Vol. 16, No. 3, p 229-240, March, 1983. 8 Fig, 1 Tab, 15 Ref. DACW29-79-R-0221.

Descriptors: *Estuaries, *Tidal effects, Velocity, Tidal prism, Water exchange, Fluctuations, Water currents, Lake Pontchartrain, Louisiana.

Estuarine water movements occur over a broad range of time scales. In this study, moored current meter data were used to investigate water volume exchange in the tidal passes of Lake Pontchartrain, Louisiana on the tidal and subtidal time scales. A calibration technique, employing cross-channel measurements of water velocity, was used to calibrate the moored current meters, thus allowing for calculation of volume flow over a 35-day period. The local diurnal tide accounted for 50% of the total volume exchange, the rest being due to subtidal events (frontal passage). This subtidal exchange occurs primarily as large-scale events characterized by volume fluxes up to six times greater than the normal tidal prism. Neglecting this subtidal component in the determination of the volume fluxes for a system such as Lake Pontchartrain, could result in substantial underestimation (by as much as 50%) of these volumes and their corresponding material fluxes. SOME FEATURES OF THE DYNAMIC STRUCTURE OF A DEEP ESTUARY,
National Oceanic and Atmospheric Administration, Rockville, MD. Office of Marine Pollution Assessment.
M. Devine.
Estuarine, Coastal and Shelf Science, Vol. 16, No. 3, p 271-289, March, 1983. 3 Fig, 28 Ref.

Descriptors: *Estuaries, *Boundary layers, Mathematical models, Velocity, Salinity, Stratification, Upwelling, Mixing, River flow, Path of pollutants, Flushing, Dynamics.

A boundary layer formulation for the dynamic structure of a deep estuary is developed. Cross-stream averages are used, but the boundary layer structure is shown to depend on the cross-stream geostrophic constraint. A similarity transformation and a weighted residual method are used to derive an approximate solution for the velocity and salinity structure of the upper layer. This solution indicates that, in the central regime of the estuary, outflow extends through the entire halocline. Inflow takes place in a much less stratified lower layer, and mass exchange between the layers is by upwelling. This structure is modified in the outer regime of the estuary, where mixing between the layers develops, and in the inner regime, where a sharp halocline develops and where the dynamics are dominated by river runoff. The implications of the dynamics for the flushing process and for pollutant movement and dispersion are discussed. (Author's abstract)

STUDIES ON THE BEHAVIOUR OF NUTRIENTS IN THE MANDOVI ESTUARY DURING PREMONSOON,
National Inst. of Oceanography, Panaji (India).
S. N. De Sousa.
Estuarine, Coastal and Shelf Science, Vol. 16, No. 3, p 299-308, March, 1983. 8 Fig, 1 Tab, 17 Ref.

Descriptors: *Estuaries, *Nutrients, Silicates, Nitrates, Phosphates, Salinity, Mixing, Industrial wastes, Water pollution, India.

Behavior of silicate, nitrate and phosphate in the Mandovi Estuary (India) was studied during the premonsoon season. The study shows that silicate is removed from the water column while nitrate showed an internal source. This nitrate source has been identified as the wash water from an iron ore screening plant which discharges the muddy waste directly into the river. Applying mixing relations, the distribution of this nitrate both up- and downstream of the outfall has been studied. Phosphate showed very low concentrations in the low salinity region; however, its concentration increased slightly towards the higher salinity region. (Author's abstract)

Descriptors: *Estuaries, *Salt marshes, *Tidal exchange, *Nutrient cycling, Nitrites, Phosphorus, Nitrogen, Ammonium, Fluctuations, Seasonal variation, Wave action, Particulates, Solute transport, Sediment transport, Vegetation, Chesapeake Bay.

A 22-month study was conducted to determine the exchange of nitrogen and phosphorus between a mesohaline vegetated marsh in the Carter's Creek area of Virginia and the surrounding estuary, focusing on the role of the vegetated marsh surface in the processing of these constituents. On an annual basis there was a removal of NH4(+), PO4(3-), NO3(-), dissolved organic nitrogen, dissolved organic phosphorus, particulate nitrogen and particulate phosphorus from the tidal water as it resided on the vegetated marsh. Only nitrite was transported from the marsh to the estuary. Most of the nitrogen and phosphorus species showed distinct seasonal trends with respect to the direction of transport except nitrate and orthophosphate. The ammonium flux data indicates that this nutrient was removed from the inundating water during late spring and fall, with a slight release of this constituent into the tidal water during the late summer. The transport of nitrite was from the estuary to the marsh for most of the year except during the summer. The largest re
particulate nitrogen and phosphorus from
water occurred during the summer mon
the turbidity of the tidal water was high
cially when wave scouring of the mudfla
material into the water column. A loss o
late nitrogen from the marsh to the est
evident during the fall and winter. (Aut

Texas.

Water flows, concentrations of total (TO
solved (DOC), and particulate (POC)
carbon and seston were monitored for
periods in the single creek draining a 270-h
tina patens - Distichlis spicata marsh on th
Texas coast. Rainfall, creek water flows, an
levels in the creek and on the marsh wer
ured by recording instruments. Rainfall ac
for most marsh flooding, and water outfl
significantly correlated with both rainf
marsh water level. Creek flows were predo
ly outward because microtopographic featu
dense vegetation restricted overmarsh wate
and thereby reduced tidal flooding while ex
the time of precipitation runoff. Concentra
organic carbon in water leaving the mars
highest in spring and summer and average
21.41 and 3.35 mg/l of TOC, DOC and
respectively. These were 9.34, 9.93 and 0.0
respectively, higher than bay water. Mos
was 0.3-28 micro m in diameter. Seston

leaving the marsh was 95% amorphous
the rest was plankton, grass particles and
lets. Loss of organic carbon was directly
d with net water flux, and thus rainfall
d for most carbon loss. Net carbon loss
196 kg TOC, 150 kg DOC and 32 kg
day. Net annual loss was 2.4-5.5% of net
imary productivity (NAPP), or 21.55-
TOC/sq m/yr. Export from this marsh
in the range found for other marshes and
collectively indicate that coastal marshes
osing as much organic carbon as has been
l by indirect measurements. The discrep-
ween potential and realized export is ex-
y the fact that export is not a simple
of excess detritus by tidal action but is
nplicated process mediated by the interac-
dditional factors such as rainfall, vegeta-
cture, microtopographic variation and de-
ion, which can serve to reduce the
nd quality of NAPP exported. (Author's

ion, Solute transport, Salinity.

method for the determination of dis-
mic acid based on carbon analysis is
This method was used to measure the
n of dissolved humic acids in seven
ain estuaries located in the middle-Atlan-
States. Results indicate that 100% of the
humic acid was removed during estuar-
g, although concurrent measurements of
organic carbon showed either produc-

tion or conservative behavior in regions of the estuary where humic acid removal was observed. It is apparent from these observations that removal of dissolved humic acid is a minor part of the estuarine transport of dissolved organic carbon. Laboratory experiments carried out by mixing river water with sea water demonstrated that salt-induced removal of dissolved humic acid was insignificant in two of three estuaries studied. These results suggest in situ removal of dissolved humic acid may not be universally caused by increasing estuarine salinity. (Author's abstract)

DISTRIBUTION OF SOME METALLIC ELEMENTS IN EELGRASS (ZOSTERA MARINA L.) AND SEDIMENT IN THE LIMFJORD, DENMARK,
Aarhus Univ. (Denmark). Botanical Inst.
H. Brix, and J. E. Lyngby.
Journal of Estuarine, Coastal and Shelf Science, Vol. 16, No. 4, p 455-467, April, 1983. 8 Fig, 3 Tab, 34 Ref.

Descriptors: *Submerged plants, *Sea grasses, *Metals, Sediments, Calcium, Cadmium, Copper, Iron, Potassium, Magnesium, Manganese, Sodium, Lead, Zinc, Mineral cycling, Brackish water, Limfjord, Denmark.

The distribution of Ca, Cd, Cu, Fe, K, Mg, Mn, Na, Pb and Zn in different parts of eelgrass (Zostera marina L.) and sediment (0-25 cm depth) collected at three locations in the Limfjord, Denmark, were investigated. Eelgrass plants were divided into roots, rhizomes, stems and leaves according to age, and the metal content in each fraction was determined. The distribution pattern of the metals could be divided into separate groups according to the following criteria: (i) the age-dependent distribution pattern of the metals in the leaves (the concentrations of Ca, Cd, Fe, Mg, Mn, Na, Pb and Zn increased with the age of the leaves; the concentrations of Cu and K decreased with age); (ii) the concentration level of the metals in the roots compared to that in the rhizomes (Ca, Cd, Cu, Fe, Mn, Pb and Zn concentrations were highest in the roots; K, Mg and Na concentrations were highest in rhizomes); (iii) the concentration level of the metals in the 'stem' -fraction compared to that in the youngest leaf (the concentration of Fe, K, Mg, Na and Pb were highest in the 'stem' -fraction; the concentrations of Ca, Cd, Mn and Zn were highest in the youngest leaf). The distribution pattern of the metals are discussed, especially in relation to the gross morphology of eelgrass. Finally, the relatively large quantity of metals tied up in the eelgrass biomass at the three localities indicated that the eelgrass beds most likely exerted a significant role in the metal cycling in the Limfjord. ON THE PREDICTABILITY OF THE 137CS DISTRIBUTION IN THE SEVERN ESTUARY,
Washington Univ., Seattle. School of Oceanography.
M. Rattray, Jr., and R. J. Uncles.
Journal of Estuarine, Coastal and Shelf Science, Vol. 16, No. 5, p 475-487, May, 1983. 6 Fig, 3 Tab, 11 Ref.

Descriptors: *Estuaries, *Water circulation, Dispersion, Mathematical models, Salinity, Stratification, Runoff, Radioactive tracers, Cesium, Stokes drift, Severn Estuary.

The observed distribution of Cs137 resulting from known sources in the Severn Estuary permits the testing of simple predictive models for the one-dimensional distribution of non-conservative substances in an estuary. These models either use a known distribution of salinity to infer corresponding ones for other substances, or else directly solve mass balance equations utilizing previously determined dispersion coefficients. Both methods are shown to provide results comparing favorably with observations. Stokes drift plays an important role in the circulation of the Severn. A modified densimetric Froude number, including this drift, is therefore used to estimate the circulation and stratification of the estuary. A new equation is used for calculating the Cs137 distribution from the observed salinity distribution. It generalizes previous formulations to permit variation of the net runoff with position along the estuary. (Author's abstract)

THE TRANSPORT OF BACTERIA IN THE SEDIMENTS OF A TEMPERATE MARSH,
Smithsonian Institution, Edgewater, MD. Chesapeake Bay Center for Environmental Studies.
P. A. Rublee, S. M. Merkel, and M. A. Faust.
Journal of Estuarine, Coastal and Shelf Science, Vol. 16, No. 5, p 501-509, May, 1983. 4 Fig, 1 Tab, 17 Ref. DEB 7911563.

Descriptors: *Bacteria, *Salt marshes, Sediment transport, Estuaries, Interstitial water, Tidewater, Biomass, Particulates, Organic material, Marshes.

The number of bacteria in sediments, interstitial water and overlying tidal water of an oligohaline marsh system are about 109, 106 and 106 cells/cu cm, respectively. Average cell size in the overlying water (about 0.06 cu micro m), is much smaller than that in sediments and interstitial water (about 0.18 cu micro m). Most bacteria cells in sediments are bound to sediment particles and less than 1% of the cells were displaced by percolating water through sediment columns. Concentration of bacteria in flooding tidal waters is generally higher than that in ebbing waters. Movement of bacterial biomass does not appear to be a significant mechanism of particulate organic transport in marsh sediments and marsh sediments do not appear to be a source of suspended bacteria for estuaries. Separation Science and Technology, Vol. 18, No. 3, p 229-237, 1983. 6 Fig, 1 Tab, 9 Ref.

Descriptors: *Reverse osmosis, *Membrane processes, Desalination, Mathematical models, Simulation, Membranes, Permeability, Flow.

A mathematical model is developed to describe the transport phenomena in reverse osmosis desalination with composite membranes, which consist of two components having different value of A and B, where A is a membrane constant for water flow and B is a solute permeation constant. The composite membrane is composed of a dispersed phase (Component I) and a matrix phase (Component II). It is found possible to fabricate a high performance membrane by casting a film composed of a small particle size of Component II with a large value of A and a very thin Component I with a small value of B, in the practical separation technique. 3B. Water Yield Improvement

USING HISTORICAL COMPARISONS IN EVALUATING CLOUD SEEDING OPERATIONS,

Rochester Univ., NY. Dept. of Statistics.
K. R. Gabriel, and D. Petrondas.
Journal of Climate and Applied Meteorology, Vol. 22, No. 4, p. 626-631, April, 1983. 8 Tab, 6 Ref.

Descriptors: *Cloud seeding, *Precipitation, Statistical methods, Simulation, Weather modification, History.

Cloud seeding operations are often evaluated by comparing precipitation during operations with records of previous 'historical' precipitation. Extensive worldwide precipitation records are used to examine whether the usual statistical techniques may be validly applied to comparisons of precipitation in successive years, as is done in the evaluations of cloud seeding. To study the operating characteristics of tests of significance, records of annual precipitation for successive years at a number of stations are divided into two periods, the first of which is regarded as 'historical' and the second as ' operational.' In this way, a pseudo-experiment can be simulated in which there is no effect of seeding. It is concluded that the chance of finding a significant seeding effect in the absence of seeding is usually well above the nominal significance level used. It is therefore recommend that P-values from such operational/historical comparisons be treated very cautiously, possibly by multiplying them by a suitable factor, e.g., a 5% significant result of such a comparison should really be regarded as more nearly as 10% significant. 3C. Use Of Water Of Impaired Quality

CARBONATE DEPOSITS IN VACUUM PUMPS OF O'NEILL PUMPING PLANT, CALIFORNIA,
Water and Power Resources Service, Sacramento, CA.
N. P. Prokopovich, and E. G. Robles, Jr.
Bulletin of the Association of Engineering Geologists, Vol. 20, No. 2, p 197-203, May 1983. 9 Fig, 1 Tab, 3 Ref.

Descriptors: *Pumps, *Calcium carbonate, *Scaling, Cooling water, Carbon dioxide, Vacuum pumps, Reservoir operations, California.

The O'Neil Pumping-(Generating) Plant was designed to pump-lift mostly irrigational water from the Delta-Mendota Canal into O'Neil Forebay Reservoir. After a few months of operation pumping toe drain water to the pumping plant for use as cooling water, a small vacuum pump failed. Inspection of the dismantled pump revealed intense, buff-colored incrustations on its interior surface. The crust was strongly indurated with the steel body of the pump and was usually 0.5 mm thick, and locally 2-3 mm thick. Chemical tests of the scrapings indicate their composition to be of calcium carbonate with traces of limonitic pigment. Toe drain water is extremely rich in carbon dioxide and bicarbonate, and the concentration of both drops notably in the discharged cooling water. The original source of O'Neill water is the relatively soft, but highly turbid waters of the Sacramento-San Joaquin Delta. During storage in O'Neill and San Luis Reservoirs (both of which are underlain by calcareous deposits) the deltaic water dissolves variable amounts of soluble salts, particularly bicarbonates, and the decay of aquatic vegetation in the reservoirs creates carbon dioxide. This hard but clean water enters the vacuum pumps and, under vacuum conditions, releases its carbon dioxide, breaking soluble bicarbonates into carbon dioxide, water, and insoluble carbonate which is deposited on the pumps' interior surfaces. SALINE WATER USE PROSPECTS: COLORADO RIVER,
Bureau of Reclamation, Denver, CO. Colorado River Water Quality Office.
M. B. Bessler.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 2, p 221-231, June, 1983. 4 Fig, 4 Tab, 7 Ref.

Descriptors: *Saline water, *Alternative water use, Slurries, *Colorado River, River basin development, Water resources development, Economic aspects, Energy, Legal aspects.

Cost-effectiveness estimates are discussed for various alternative uses for saline water in the Colorado River Basin. Local saline water use, in areas less than 100 mi distant, for energy production looks promising, but cost-effectiveness is very sensitive to specific site conditions. In order to encourage use of saline water vs freshwater, most utilities need regulatory or financial incentives. The use of saline water for coal slurry transport appears to offer significant potential for joint use savings and reduction in the costs of salinity control. Legal issues and concerns raised about procedures for acquiring diversion rights, allocation of waste saline water among state and federal interests, and transfer of saline water across state boundaries are problems which must be addressed by the Basin states. The institutional arrangements for implementing the options lend themselves to a unique partnership between the federal government and industry. Through the federal salinity control effort, the use of desalting plants and lined evaporation ponds for ultimate disposal would require large monetary investments both in up front construction costs and in long term maintenance. If the private sector were to activate some of these alternative uses for saline water there would also be monetary investments needed. A part of the government capital, focused toward a joint venture with energy related industries, could mean decreased monetary investments for both government and industry and each would reap the rewards. A new bill to amend the 1974 Colorado River Salinity Control Act (Public Law 93-320) has been introduced recently which would permit such joint ventures to take place. (Baker-IVI)

RE-CYCLING OF INDUSTRIAL COOLING WATER,
G. B. Hill.
Water and Waste Treatment Journal, Vol. 26, No. 5, p 56-57, May, 1983. 2 Fig.

Descriptors: *Water cooling, *Water reuse, Recirculated water, Design criteria, Cooling ponds, Cooling towers, Refrigeration.

In the light of the growing costs and restrictions imposed upon industrial usage of mains water, together with the vulnerabilities exposed by supply failures, there are increasing requests for recirculatory cooling water systems. The simplest method for cooling water is the cooling pond. A spray pond extends the principle a little further, but both methods suffer from water contamination and are only suitable for cooling water received at higher temperatures. Another simple method is the atmospheric cooling frame where water is sprayed down a louvered shell through which the wind blows, mixing with the water and cooling it. Performance is dependent on weather and the system suffers from water carry-over. Chimney natural draft cooling towers have warm water released at the top of the tower falling over the large area of packing below, while air flowing up through the tower by convection cools the water. Mechanical draft cooling towers are almost independent of atmospheric conditions, other than the ambient wet bulb temperature. Air blast coolers pass heated water through tubes over which cooling air is blown by an axial flow fan. Heat transfer is assisted by fitting fins or wire on the tube outer surface. Water chillers employ the basic mechanical compression refrigeration systems of reciprocating, centrifugal or screw design. Adsorption systems are rarely used. The water cooling duty related to the water flow rate and temperature rise when passing through the plant, determines the size of equipment needed. (Baker-III)

tors: *Irrigation efficiency, *Fall irrigation, ter, Field capacity, Corn, Alfalfa, Wheat, torage, Profile water.

d availability of fuel, water supplies, and re creating interest in extending irrigation e dormant season. The amount of profile n early spring that resulted from increased water in fall was assessed at three locations oil, climate, and limited irrigation resources fall irrigation has potential as a manage-ractice. Soils were Ulysses silt loam (fine-silty, mixed, mesic Aridic Haplustoll), Amsterdam silty clay loam (fine-silty, mixed Typic Cryoboroll), and Great Bend silt loam (fine-silty, mixed Udic Haploboroll) at Tribune, Kansas, Bozeman, Montana, and Redfield, South Dakota, respectively. Crops were corn and winter wheat at Tribune; alfalfa and spring wheat at Bozeman; and alfalfa, corn, spring wheat, and winter wheat at Redfield. Differences in crop growth patterns and irrigation regimes provided a broad range of fall soil water contents at each location. Profile soil water content was sampled gravimetrically at Tribune and by neutron attenuation at Bozeman and Redfield no earlier than 10 d after fall irrigation and in early spring. By multiple regression analysis, it was established that profile water content change rate during winter (profile water at early-spring sampling minus profile water at fall sampling divided by the number of days) decreased and as available soil water in fall increased. The amounts of profile water in early spring resulting from 10 mm of additional fall profile water, calculated by using the long-term precipitation mean for 22 December through 31 March at each location (0.44, 0.54, and 0.52 mm/d for Tribune, Bozeman, and Redfield, respectively) were: 8.6, 6.8, and 5.0 mm at Tribune; 8.5, 7.5, and 6.6 mm at Bozeman; and 8.2, 7.0, and 5.8 mm at Redfield for available soil water values in fall of 30, 50, and 70%, respectively. The data and calculations show fall irrigation to be an inefficient practice for many situations, even where the antecedent profile water content is well below the 'field capacity' value. (Moore-IVI)

STATISTICAL ANALYSIS OF LINE-SOURCE SPRINKLER EXPERIMENTS AND OTHER NONRANDOMIZED EXPERIMENTS USING MULTIVARIATE METHODS,
Kansas State Univ., Manhattan. Dept. of Statistics.
D. E. Johnson, U. N. Chaudhuri, and E. T. Kanemasu.
Soil Science Society of America Journal, Vol. 47, No. 2, p 309-312, March-April, 1983. 1 Fig, 3 Tab, 4 Ref.

Descriptors: *Statistical analysis, *Sprinkler irrigation, Crop yield, Multivariate analysis, Mathematical studies.

The line-source sprinkler system provides a continuous variable soil water gradient away from a water source. The system can be used effectively to study the effects of various levels of water applied on crops, and minimizes the amount of land required for such experiments. A recent paper suggested that there was no statistical test available for comparing the effects of irrigation level on yield because irrigation levels are often applied systematically without randomization. This paper shows how multivariate methods can be used to obtain an appropriate statistical test. The method can also be used for many other nonrandomized experiments. One such experiment occurs when readings on the same experimental unit are recorded at several different time periods. Another occurs when measurements are made on several different parts of the same plant, e.g. stem, leaf, etc. The methods provide tests for equal cultivar effects; irrigation effects, and also cultivar X irrigation level interaction. HEAT REJECTION SYSTEMS: MEETING COSTS, DEMANDS AND REGULATORY REQUIREMENTS,
R. C. Rittenhouse.
Power Engineering, Vol. 87, No. 6, p 46-54, June, 1983. 6 Fig, 4 Tab.

Descriptors: *Cooling towers, *Water cooling, Cooling ponds, Powerplants, Water reuse, Wastewater treatment, Chlorination, Water management.

The heat rejection system in a power plant can offer cost savings if care is exercised in design, operation and maintenance, and if the developing need to upgrade is met with a timely response. Cooling towers may be needed for powerplants in the future because of: tightening regulations for once-through cooling; real estate and water shortages; environmental impact, and the large amounts of cooling surface which may be needed. Use of a cooling tower vs cooling lakes is considered. The potential advantages of multiple use of cooling lakes should be considered during the evaluation of types of cooling systems to be chosen for a site. Maintenance and upgrading of tower operations are important for controlling costs. Environmental regulations limiting the concentration of chlorine discharges make it imperative that utility staff people monitor the behavior of the biocide to optimize its capabilities while controlling its discharge. Water conservation or the lack of water in arid regions are the primary reasons for the development of wet/dry and dry cooling tower technology. (Baker-IVI)

HEAD LOSS AT SOIL-DRAIN ENVELOPE INTERFACES,
North Carolina State Univ. at Raleigh. Dept. of Biological and Agricultural Engineering.
D. W. Miller, and L. S. Willardson.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 2, p 221-220, June, 1983. 4 Fig, 3 Tab, 9 Ref.

Descriptors: *Head loss, *Hydraulic gradient, Hydraulic permeability, Drainage practices, Permeability, Interfaces, Laminar flow, Fluid mechanics, Earth-water interfaces, Soil physical properties.

A two-stage upward flow permeameter was designed which allowed a screen or filter fabric disk to be inserted in the center of a soil column as well as at the outlet of the permeameter. The interface was studied under two conditions: one with water passing from a porous medium through an interface and back into the same medium, and a second with water passing from a porous medium through an interface and into water ponded above the interface. A fundamental difference was found between the head loss across the two interfaces. The difference in hydraulic gradients at internal and exit interfaces was attributed to the simultaneous action of two processes: the physical restructuring of the interfacial zone as viscous drag caused soil particles or sand grains to bridge over or plug pores in the interface; and a second process, which seems to be a function of the changing ratio of viscous and inertial forces occurring as water passes through exit interfaces. The geometry of the flow paths changes dramatically during this passage and this change in turn alters the distribution of viscous shear and inertial forces acting between the water and the boundaries of individual flow paths. Head loss in soil was greater at exit interfaces than would be predicted using laminar flow theory. Water leaving the soil and entering a drain

or a very permeable drain envelope demonstrates an excess energy loss. Artificial internal interfaces in the soil do not show the same head loss as exit interfaces. Inertial energy losses seem to explain the difference in the head losses measured for the two types of interfaces. The findings suggest that high gradients at exit interface of a porous medium mean that hydraulic failure gradients may occur under flow conditions that would theoretically be stable. The effect of the large exit gradient could also reduce the apparent permeability of soil samples where only inflow and outflow heads are measured. Piezometers measuring internal hydraulic gradients in soil samples should be at least 4 cm away from the exit interface. (Baker-IVI)

SALT-WATER INTRUSION IN THE NILE DELTA,
A.-A. I. Kashef.
Ground Water, Vol. 21, No. 2, p 160-167, March-April, 1983. 4 Fig.

Descriptors: *Saline water intrusion, *Groundwater management, *Groundwater potential, Egypt, Nile River, Groundwater recharge, Irrigation water, Groundwater irrigation, Geohydrology, Land reclamation, Infiltration, Seepage.

Egypt is presently involved in a comprehensive program of land reclamation. Surface water has already been exhausted in meeting the urgent needs of agricultural expansion. Ground-water development has priority over increasing irrigation efficiency (which would take a longer time). A review of the recent investigations of the groundwater resources in the Delta aquifer is given, and an attempt is made to determine the extent of intrusion using two unconventional methods based on the available geohydrological data. The case is unique because most of this aquifer is invaded by salt water, and the major portion of its annual ground-water recharge is derived from the direct seepage from the Nile River and the huge net of irrigation canals serving about 3 million acres (approximately 11,561 sq km) of fertile land, as well as the infiltration of excess irrigation water. The annual overall groundwater recharge to the aquifer was estimated as 6.40 cu km/yr. Methods of salt-water control and various techniques of water resources management are discussed. Groundwater development may be started south of potentiometric contour +10 and along the Nile branches (if there is no conflict in water use). North of contour +10, utmost care should be observed regarding high pumping or extensive developments. It is recommended that pilot projects be started to control salt-water intrusion. (Moore-IVI)

HARMONIZING GHYBEN-HERZBERG INTERFACE WITH RIGOROUS SOLUTIONS,
A.-A. I. Kashef.
Ground Water, Vol. 21, No. 2, p 153-159, March-April, 1983. 1 Fig, 2 Tab, 8 Ref.

Descriptors: *Saline-freshwater interfaces, *Saline water intrusion, Mathematical studies, Groundwater management, Coastal aquifers, *Ghyben-Herzberg interface, Groundwater movement.

Ground-water management in coastal aquifers is becoming highly complex due to the increase in water demand coupled with the threat of salt-water encroachment. The salt-water/fresh-water interface produced by the natural flow of the aquifer is distorted as a result of ground-water exploitation. During the last four decades, the use of Ghyben-Herzberg (G-H) principle to determine the salt-water/fresh-water interface in coastal aquifers was questioned by many investigators due to the neglect of the water movement. Some of the highly complex solutions which were later introduced are reviewed and compared with the G-H results for a very wide range of parameters. It has been found that the G-H principle is valid for practical purposes and that the differences between location of the interface predicted by the G-H principle and those determined by the rigorous solutions may be less than the differences resulting from small errors in the field records of water levels. For exceptionally high natural velocities and for more precision within the zones very close to the shore, two simple equations derived on the basis of the rigorous solutions are given. Each equation is written in terms of the popular G-H solution with a correction factor added. The results of these equations are tabulated in dimensionless values for practical use. Moreover, the extent and size of the fresh-water lens can be determined from the field records of one or two shallow observation wells. An example is given to clarify the procedure. (Moore-IVI)

Descriptors: *Recharge basins, *Artificial recharge, *Ogallala aquifer, *Playas, Storm runoff, Groundwater recharge, Permeability, Turbidity, *Texas, High Plains.

A 0.20-ha (0.5-acre) recharge basin was tested for conserving storm runoff that collected in a 16-ha (40-acre) playa in the Southern High Plains, southwest of Amarillo, Texas. The basin was constructed by removing 1.2 m (4 ft) of the slowly permeable Pullman soil to expose a 0.3 (1-ft) thick caliche layer overlying permeable sediments. Turbid water was pumped from the playa to the basin during eight tests over a 7-yr interval. Average recharge rate during 187 days of flooding was 0.373 m/d (1.22 ft/day). After three recharge tests during the first year, no maintenance was done to the basin bottom. Research showed that recharge basins could be an effective technique for partial
ishing the depleted Ogallala Aquifer. (M

Lead was determined in the polluted tropical waters of Guanabara Bay (Rio de Janeiro, Brazil) by anodic stripping voltammetry in the differential pulse and linear sweep modes. The quantitative implications of heavy metal determinations in polluted sea water and some electrochemical parameters concerning the two voltammetric modes are discussed, as well as the efficiency of the hanging mercury drop mercury film electrodes. Values found for total lead concentration range between 0.07 and 5.4 microgram/kg. Some data are also presented for copper which was shown to interfere at pH greater than 2. (Wheatley-IVI)

INTERLABORATORY STUDY ON DETERMINATION OF 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN IN FISH,
Health and Welfare Canada, Ottawa (Ontario). Health Protection Branch.
J. J. Ryan, J. C. Pilon, H. B. S. Conacher, and D. Firestone.
Journal of the Association of Official Analytical Chemists, Vol. 66, No. 3, p 700-707, May, 1983. 7 Tab, 12 Ref.

Descriptors: *Dioxins, *Chemical analysis, *Fish, Great Lakes, Water pollution effects, Tetrachlorodibenzo-p-dioxin, Chlorinated hydrocarbons.

An interlaboratory round robin study was carried out to estimate the reliability of data on 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in fish. Using different methods, 13 laboratories (4 Canadian, 9 American) agreed to analyze 4 fish samples; 3 were Great Lakes salmonids containing bio-incurred levels of TCDD below 100 ppt and the fourth was an ocean fish fillet containing no measurable TCDD. Samples were sent as freeze-dried portions as it was shown that no change of TCDD occurred by this sample preparation. Results were normalized between laboratories by supplying each with an aliquot of the same 2,3,7,8-TCDD standard. Eight laboratories reported a set of results of which one set was rejected. Values from the 7 remaining laboratories for the 3 positive fish showed mean concentrations in pg/g (ppt) and (CV,%) of 61.2 (13.9), 30.4 (18.4) and 32.3 (25.4). Detection limits averaged 3.6 ppt and ranged between 1 and 10 ppt. No significant differences appeared in the concentration of 2,3,7,8-TCDD in fish samples from methods differing in the use of: (i) digestion or extraction techniques, (ii) high or low resolution mass spectrometry, and (iii) isomer specific or nonspecific separations. Overall recovery values using internal standards varied greatly (29-109%) even within the same laboratory and pointed to the need to use an internal standard to obtain precise results. Agreement among laboratories was good considering the level quantitated (ppt) and the diverse methodology. (Author's abstract)

EXTRACTION AND CLEANUP PROCEDURES FOR DETERMINATION OF DIARYLPHOSPHATES IN FISH, SEDIMENT, AND WATER SAMPLES,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
D. C. G. Muir, and N. P. Grift.
Journal of the Association of Official Analytical Chemists, Vol. 66, No. 3, p 684-690, May, 1983. 3 Fig, 6 Tab, 12 Ref.

Descriptors: *Diarylphosphates, *Gas liquid chromatography, *Chemical analysis, Fish, Water pollution, Sediments, Phosphates, *Pollutant identification.

Methods for determination of triaryl/alkylphosphates (TAPs) in water, fish, and sediment were extended to determination of the diarylphosphate (DAP) degradation products. DAPs were extracted from water (adjusted to pH 0.5) by use of XAD-2 resin and determined by gas-liquid chromatography (GLC) as butyl esters. Recoveries of diphenylphosphate (DPP) and o-, m-, p-dicresylphosphates (DoCP, DmCP, DpCP) were > 95% in water samples fortified at 1, 10, and 50 microgram/L. DAPs were extracted from fish with methanol and the extracts were cleaned up on reverse phase (C18) silica cartridges. Recoveries were > 87% for DPP, DoCP, DmCP, and DpCP in fish muscle fortified at 50, 100, and 500 ng/g. Sediments were refluxed with aqueous methanol and DAPs were recovered by use of XAD-2 resin. Recoveries of DAPs from sediments fortified at 50 and 100 ng/g were >76%. Interferences (1-10 ng/g) from phosphorous or nitrogen-containing GLC prevented sub-ng/g level analysis for DAPs in sediment and fish extracts. (Author's abstract)

HIGH RESOLUTION GAS CHROMATOGRAPHY OF CHLORINATED BENZENES,
Food and Drug Administration, Washington, DC. Div. of Chemical Technology.
L. J. Miller, T. J. Farrell, and B. J. Puma.
Journal of the Association of Official Analytical Chemists, Vol. 66, No. 3, p 677-683, May, 1983. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Benzenes, *Chlorinated hydrocarbons, *Gas chromatography, Water pollution, Chemical analysis, Chlorinated benzenes, *Pollutant identification.

Chlorinated benzenes are found as contaminants in foods and water. These high production volume chemicals may enter the environment and food chain through improper waste disposal, use as solvents and odor control agents, or as impurities in other industrial chemicals. Because of differences in the electron capture responses of the isomers at each chlorination level, residue quantitation requires the separation of all 12 chlorobenzenes. Resolution was studied on packed and capillary columns coated with Kovats' C-87 H-176 hydrocarbon, OV-101, OV-210, OV-17, and Carbowax 20M. Satisfactory resolution of all 12 chlorobenzenes was obtained with a Carbowax 20M-coated 20 m x 0.25 mm id capillary column operated isothermally at 120 degrees C. (Author's abstract)
W84-01064

GAS-LIQUID CHROMATOGRAPHIC DETERMINATION OF S,S,S,-TRIBUTYL PHOSPHOROTRITHIOATE (DEF) IN WATER AND FISH TISSUE,
Columbia National Fisheries Research Lab., MO.
R. G. Lehmann, L. M. Smith, R. H. Wiedmeyer, and J. D. Petty.
Journal of the Association of Official Analytical Chemists, Vol. 66, No. 3, p 673-676, May 1983. 2 Fig, 2 Tab, 9 Ref.

Descriptors: *Defoliants, *Chemical analysis, *Gas chromatography, Fish, Agricultural chemicals, Water pollution, *Pollutant identification.

The widespread use of the cotton defoliant S,S,S-tributylphosphorotrithioate (DEF) suggests the possibility for contamination of freshwater fisheries from runoff and possibly from aerial transport. Methods are described for determination of DEF at levels as low as 5 parts per billion in fish and 200

parts per trillion in water. Fish tissue extracts are subjected to gel permeation chromatography (GPC) and silica gel chromatography; water samples are extracted with dichloromethane. Analyses are carried out by gas chromatography in which either electron capture or thermionic specific detectors are used. The applicability of the methods is demonstrated by analyses of water and fish samples from exposure studies. (Moore-IVI)

LIQUID CHROMATOGRAPHIC DETERMINATION OF GLYPHOSATE IN FORTIFIED SOIL AND WATER SAMPLES,
Agricultural Research Service, Beltsville, MD. Weed Science Laboratory.
R. L. Glass.
Journal of Agricultural & Food Chemistry, Vol. 31, No. 2, p 280-282, March-April, 1983. 2 Fig, 2 Tab.

Descriptors: *Glyphosate, *Chemical analysis, Herbicides, Chromatography, Soil analysis, Pesticide residues, *Pollutant identification.

A high-performance liquid chromatographic (HPLC) method which used fluorescence detection and an amine phase column is described for the determination of glyphosate in fortified soil and water samples after the derivatization of the herbicide. Glyphosate was extracted and subsequently separated with Bio-Rad AG 1-X8 anion-exchange resin (HC03(-)form) prior to derivatizing with the fluorogenic labeling reagent, 9-fluorenylmethyl chloroformate (FMOCCI). The rate of conversion of glyphosate to the glyphosate-FMOCCL derivative was about 60%. The minimum levels of detection for glyphosate were 10 ppb in fortified water, 5 ppm in a sandy loam soil, and 50 ppm in a clay loam soil. Recoveries of glyphosate were greater than 90% in water fortified at 20 ppb-4 ppm, 55% in the sandy loam soil, and about 20% in the clay loam soil fortified at 200 ppm. In comparison to other reported methods this HPLC method is simpler, faster, and specific for glyphosate. (Author's abstract)

LESSONS FROM THE SILICA 'DECLINE' IN LAKE MICHIGAN,
Minnesota Univ., Minneapolis. Limnological Research Center.
J. Shapiro, and E. B. Swain.
Science, Vol. 221, No. 4609, p 457-459, July, 1983. 1 Fig, 1 Tab, 12 Ref.

Descriptors: *Water analysis, *Silica, *Lake Michigan, Chicago, Water treatment facilities, Chemical composition, Lakes.

Data obtained from water treatment plants on Lake Michigan were analyzed to see whether a trend could be documented regarding silica concentration in the lake. The analysis was made of the longest post-1948 periods of consistent SiO2 analysis at Chicago, which were 1949-1967 and 1971-1978. Municipal water analyses appear to document some trends, but the results continue to be equivocal on the question of whether Lake Michigan is experiencing progressive change in SiO2 concentration, dissolved or total. In the past, studies have been made which concluded that there was a decline in silica content in the lake. This effort suggests that this purported decline was due to changes in analytical methods and laboratories rather than due to a real change in the chemical composition of the lake's water. (Baker-IVI)

DETERMINATION OF CARBOSULFAN AND CARBOFURAN RESIDUES IN PLANTS, SOIL, AND WATER BY GAS CHROMATOGRAPHY,
FMC Corp., Richmond, CA. Agricultural Chemical Group.
B. C. Leppert, J. C. Markle, R. C. Helt, and G. H. Fujie.
Journal of Agricultural and Food Chemistry, Vol. 31, No. 2, p 220-223, March-April, 1983. 3 Fig, 1 Tab, 8 Ref.

Descriptors: *Pesticide residues, *Chemical analysis, Water analysis, *Carbosulfan, *Carbofuran, Gas chromatography, Soil contamination, *Pollutant identification.

Analytical procedures are described for the determination of carbosulfan and carbofuran residues in various crops, in soil, and in water. The quantitative methods involve extraction of residues using hexane-2-propanol or methanol-buffered water followed by column cleanup using Florisil, gel permeation, and Darco-Attaclay plus aluminum oxide, each column alone or in combination with each other. Residues of carbosulfan and carbofuran are detected by gas-liquid chromatography using a nitrogen-selective detector. Good recoveries are achieved with check samples fortified at the 0.05-ppm level with crops and soil and at the 0.01-ppm level with water. (Author's abstract)

ENVIRONMENTAL APPLICATIONS OF CAPILLARY GC COLUMNS,
Versar, Inc., Springfield, VA.
S. M. Sonchik.
Journal of Chromatographic Science, Vol. 21, No. 3, p 106-110, March, 1983. 7 Fig, 17 Ref.

Descriptors: *Water analysis, *Pollutant identification, *Gas chromatography, *Capillary analysis, Hazardous materials, Hydrocarbons, *Polychlorinated biphenyls.

Several environmental applications of capillary gas chromatography (GC) analysis using the high resolution achieved with open tubular columns are presented. Suspected environmental problems in landfills, abandoned or active sites, can be verified through the identification of a hydrocarbon layer found on drainage ditch water or in well water using a GC determination of the range of hydrocarbon boiling points to distinguish between gasoline, kerosene, jet fuel or heating oil. The high resolution of the complex hydrocarbon mixture can identify the spill source through careful comparison with possible source materials for subtle differences in mixtures. High resolution GC has also been used in the analysis of PCBs in complex environmental matrices and in the analysis of priority pollutants where the speed of the analysis is important. Not only is capillary analysis quicker than the analysis by packed-column GC/MS, but the fused silica column has the additional advantage of being able to extend directly to the MS ion source. An additional application is in the identification of combustion products from Thermal Destruction Units requiring high resolution separation of the chemical compounds. (Baker-IVI)

MINERALIZATION OF ORGANIC MATTER IN WATER BY U.V. RADIATION,
Ceskoslovenska Akademie Ved, Prague. Hydrobiologicka Lab.
P. Blazka, and L. Prochazkova.
Water Research, Vol. 17, No. 4, p 355-364, April, 1983. 9 Fig, 8 Tab, 23 Ref.

Descriptors: *Mineralization, *Ultraviolet radiation, Water analysis, Hydrogen ion concentration, Carbon dioxide, Oxidation process.

The conditions for the optimum yield of carbon dioxide in the mineralization of organic matter in water were tested and the relative optimum procedure was outlined. Of all substances tested the greatest difficulties were encountered with the purine bases. Their quantitative mineralization was achieved only by the highest irradiation intensities and/or prolonged irradiation. An evident relationship of mineralization and pH was found in urea and thiourea. Adsorption of proteins on silica and glass apparatus was suppressed by phosphoric acid, but a correction of the amount of organic carbon recovered in the blank still had to be applied in protein rich samples. A SENSITIVE METHOD FOR MEASURING ORGANIC CARBON IN SEDIMENT,
Tokyo Univ. (Japan). Faculty of Pharmaceutical Sciences.
J. Suzuki, Y. Yokoyama, Y. Unno, and S. Suzuki.
Water Research, Vol. 17, No. 4, p 431-434, April, 1983. 2 Fig, 3 Tab, 8 Ref.

Descriptors: *Organic carbon, *Sediments, River beds, Analytical methods, Pollutant identification, Solvent extraction.

In order to determine organic carbon in sediments, a sensitive method was devised by the combination of an ordinary wet combustion and TOC analyzer for aqueous samples. The carbon dioxide evolved by wet combustion was absorbed into 0.2 N NaOH solution and determined with a TOC analyzer. The accuracy and the determination limit of the method were determined. Carbon ranges from 0.4 to 48 mg were determined accurately without interference of chlorine and sulfur. This method was applied to the study of the composition of river sediment on the basis of extractability by various solvents. (Author's abstract)

VELOCITY EQUATION FOR WATER QUALITY MODELING IN GEORGIA,
Georgia Dept. of Natural Resources, Atlanta. Environmental Protection Div.
R. Burke, III.
Water Resources Bulletin, Vol. 19, No. 2, p 271-276, April, 1983. 3 Fig, 2 Tab, 12 Ref.

Descriptors: *Hydrologic models, *Water pollution control, *Statistical analysis, *Georgia, Physiographic provinces, Stream discharge, Soil types, Velocity, Mathematical studies.

Tabletop water quality modeling still plays an important role in the water pollution control activities of the Georgia Environmental Protection Division. Tabletop models are those developed without the aid of extensive field data. One important component of GEORGIA DOSAG, our basic water quality model, is the equation used to predict flow through velocity. However, Georgia is characterized by wide physiographic diversity which reduces the effectiveness of uncalibrated velocity equations. Using 15 years of accumulated time-of-travel studies, a series of empirical velocity equations were developed and calibrated to various physiographic conditions in Georgia. Equations are available for each major soil province and for three stream flow ranges within each province - $Q<100$cfs, $100<Q<1000$ cfs, and $Q>1000$ cfs. Now, in the absence of extensive field data, we have data based velocity equations which can be tailored to each site under study. (Author's abstract)

PREDICTION OF CHLOROPHYLL A CONCENTRATIONS IN FLORIDA LAKES: THE IMPORTANCE OF PHOSPHORUS AND NITROGEN,
Florida Univ., Gainesville. School of Forest Resources and Conservation.
D. E. Canfield, Jr.
Water Resources Bulletin, Vol. 19, No. 2, p 255-262, April, 1983. 2 Fig, 3 Tab, 39 Ref.

Descriptors: *Chlorophyll a, *Nitrogen, *Phosphorus, Florida, Eutrophic lakes, Mathematical models, Limiting nutrients, Algal growth.

Models for the prediction of chlorophyll a concentrations were developed and tested using data on 223 Florida lakes. A statistical analysis showed that the best model was log (Chl a)= -2.49 + 0.269 log (TP) + 1.06 log (TN/TP) + 1.33 log (TP) where Chl a is the chlorophyll a concentration (mg/cu m), TP is the total phosphorus concentration (mg/cu m) and TN is the total nitrogen concentration (mg/cu m). The model yields unbiased estimates of chlorophyll a concentrations over a wide range of lake types and has a 95% confidence interval of 29-319 percent of the calculated chlorophyll a concentrations. Other models, especially the published Dillon-Rigler and Jones-Bachmann phosphorus-chlorophyll models, are less precise when applied to Florida lakes. The data support the hypothesis that nitrogen is an important limiting nutrient in hypereutrophic lakes. (Author's abstract)

BIOLOGICAL MONITORING OF BLUEGILL ACTIVITY,
Air Force Environmental Hazards Branch, Wright-Patterson AFB, OH. Toxic Hazards Div.
J. W. Fisher, R. A. Dilego, M. E. Putnam, J. M. Livingston, and D. L. Geiger.
Water Resources Bulletin, Vol. 19, No. 2, p 211-215, April, 1983. 3 Fig, 1 Tab, 11 Ref.

Descriptors: *Bluegills, *Bioindicators, *Water pollution effects, Hydrocarbons, Fish behavior, Monitoring, Water quality.

Bluegills were exposed for one hour to 0.2 or 2.3 mg/liter water soluble fraction (WSF) of JP-4 in a testing chamber designed to contain individual fish. A strain gage paddle was used to monitor activity. Whole body movement of individual fish did not change appreciably during exposure to either 0.2 or 2.3 mg/liter WSF-JP-4. Strength of pectoral fin movement, accounting for the majority of the fish behavior, increased in six of ten individuals exposed to 2.3 mg/liter WSF-JP-4. Pectoral fanning may be a useful parameter to indirectly assess water quality. (Author's abstract)

USE OF THE FRESHWATER CLAM CORBICULA MANILENSIS AS A MONITOR FOR ORGANOCHLORINE PESTICIDES,
Montgomery (James M.), Inc., Pasadena, CA.
D. M. Hartley, and J. B. Johnson.
Bulletin of Environmental Contamination and Toxicology, Vol. 31, No. 1, p 33-40, July, 1983. 2 Fig, 1 Tab, 25 Ref.

Descriptors: *Pesticides, *Clams, *Monitoring, Chlorinated hydrocarbons, Biological magnification, Bioindicators.

Among the bivalve species in American freshwaters is the Asiatic clam, Corbicula manilensis.

Corbicula offers several advantages as an organism for toxicity testing. It tolerates removal from water for reasonably long periods of time, it can be easily handled in the laboratory and it survives in aquaria without food for periods of up to 6 mo. The bioaccumulation of organochlorine pesticides by Corbicula taken for natural bed, incubated in an aquarium to permit self-cleaning and temporarily implanted in cages in a river was assayed in order to explore the use of temporarily implanted Corbicula for measurement of persistent pollutants in freshwater environments. Eight pesticides, aldrin, dieldrin, hexachlorocyclohexane, lindane, alpha-chlordane, gamma-chlordane, heptachlor, and heptachlor epoxide, were bioconcentrated in clam fat. A period of at least 18 days was required before pesticides in the clam fat came to equilibrium with the pesticide in the water. (Moore-IVI)

USE OF CHROMATICITY IN REMOTE MEASUREMENTS OF WATER QUALITY,
R. P. Bukata, J. E. Bruton, and J. H. Jerome.
Remote Sensing of Environment, Vol. 13, No. 2, p 161-177, May, 1983. 14 Fig, 20 Ref.

Descriptors: *Remote sensing, *Water quality, Lake Ontario, Upwelling, Turbidity, Chromaticity, Chlorophyll a, Organic carbon, Minerals, Optical properties.

The optical cross sections for Lake Ontario water masses have been utilized to study the use of chromaticity analyses for predicting water quality parameters in a water mass which is comprised of chlorophyll, suspended mineral, and dissolved organic carbon (DOC) concentrations. The analyses appear to indicate a very restricted range of such applications. For water masses containing substantial amounts of chlorophyll a or suspended mineral, chromaticity analyses are almost totally ambiguous even if the DOC concentration is known. If the DOC concentration is either known or may be inferred, chromaticity analyses may provide a distinction between clear and turbid waters, but the concentration creating the turbidity would be in doubt. For water masses in which the suspended mineral concentration is know to be moderate, and the DOC concentration is either know or can be estimated, small concentrations of chlorophyll a may be estimated to within a factor of 2. EVALUATION OF EXTRACTION TECHNIQUES FOR THE DETERMINATION OF HEAVY METALS IN RIVER SEDIMENTS,
Gifu Prefecture Research Inst. for Environmental Pollution, Yabuta (Japan).
N. Watanabe, Y. Yasuda, K. Kato, T. Nakamura, and K. Shimokawa.
Japanese Journal of Limnology, Vol. 44, No. 2, p 123-131, April, 1983. 7 Fig, 3 Tab, 25 Ref.

Descriptors: *Heavy metals, *Sediments, Extraction, Water pollution, Copper, Lead, Cadmium.

In order to distinguish whether heavy metal contents originate from a rock matrix or pollution, six different extraction techniques for copper, lead and cadmium were studied in Nagara River sediments in Gifu Prefecture, Japan. The extraction agents were hydrochloric-nitric acid mixture (1+1), 3N hydrochloric acid solution, 0.5N hydrochloric acid solution, 6 M formic acid solution, 1N hydroxylamine hydrochloride plus 25% acetic acid solution and 0.05N ethylenediaminetetraacetic acid solution. The comparison of the six extraction techniques was conducted on the basis of the heavy metal contents originating from pollution, which was estimated by subtracting background values from total contents. For copper, 3N hydrochloric acid is preferable, but in sediments with poor ignition loss, 0.5N hydrochloric acid and 6M formic acid are recommended. 1N hydroxylamine hydrochloride plus 25% acetic acid is suitable for lead and cadmium. NEPTUNIUM AND AMERICIUM SPECIATION IN SELECTED BASALT, GRANITE, SHALE, AND TUFF GROUND WATERS,
Geological Survey, Denver, CO.
J. M. Cleveland, T. F. Rees, and K. L. Nash.
Science, Vol. 221, No. 4607, p 271-273, July, 1983. 5 Tab, 6 Ref.

Descriptors: *Waste disposal, *Radioactive wastes, *Speciation, Nuclear powerplants, Americium, Neptunium, Groundwater contamination, Basalts, Sulfates, Granites.

The chemical speciation of neptunium and americium in groundwaters associated with rock types proposed as possible hosts for nuclear waste repositories was examined. The waters used were from the Grande Ronde basalt on the Hanford reservation in Washington, Climax stock granite and tuff from the Nevada Test Site, Cretaceous shale from a rural well near Rapid City, South Dakota, and, for comparison, deionized water. Mobilization of the actinides Np(IV), Np(V), Am(III), and Pu(III) in these groundwaters was minimized by reducing conditions and by high concentrations of sulfate ion, but it is uncertain whether the effect of sulfate could prevail in all groundwaters. The presence of high concentrations of free fluoride had no discernible effect on neptunium and americium solubilities. Since characteristics of chemical composition vary with location within any given host rock type and hence are site specific, it is proposed that the chemical composition of the associated ground water and actual speciation experiments be included along with other relevant parameters as criteria in the selection of geologic sites as possible repositories for nuclear waste. (Baker-IVI)

PHOTOLYSIS OF THE AQUATIC HERBICIDE FLURIDONE IN AQUEOUS SOLUTION,
Lilly (Eli) and Co., Indianapolis, IN. Lilly Research Lab.
D. G. Saunders, and J. W. Mosier.
Journal of Agricultural and Food Chemistry, Vol. 31, No. 2, p 237-241, March-April, 1983. 7 Fig, 3 Tab, 12 Ref.

Descriptors: *Fluridone, *Herbicides, *Photolysis, Lakes, Pollutants, *Pollutant identification, Chemical analysis.

The parameters affecting the photolysis of the aquatic herbicide fluridone, in water are evaluated. The photolysis of fluridone and the formation of benzaldehyde and benzoic acid photoproducts and N-methylformamide were observed in lake and distilled water exposed to sunlight for up to 27 days. The concentration of N-methylformamide increased steadily with 74 and 36% of theory, respectively, being present in the distilled and lake water after 27 days of exposure. In lake water, 3-(trifluoromethyl)benzoic acid and benzoic acid increased steadily, reaching maximums of 33 and 40%, respectively after 21 days. Only trace amounts of the benzaldehydes were observed in both lake and distilled water after 7 days of exposure, and no benzaldehydes were detected after the 14th day. Fluridone half-lives ranged from 22 to 55 hr and were only slightly dependent on fluridone concentration, oxygen concentration, and pH. Results of photolysis experiments with the photoproducts of fluridone are also presented. (McKeon-IVI)

An analysis is presented defining the distri
an organic chemical in the water and b
estuarine system. The present structure
model is a tidally averaged two-dimension
tudinal-vertical) main channel interacting
eral embayments. The water column, se
into two layers to incorporate the typical
circulation, interacts with a bed which
segmented into two layers, an active
layer and a deeper stationary bed. Ad
desorption kinetics are included which, in
of Kepone distribution of the James Ri
assumed to be at equilibrium. Both steady
well as time-variable conditions are anal
calibrate the model to reproduce prese
served concentrations of Kepone. A proc
analysis to address the problem of organi
cals in estuaries has been structured. Th
dure involves a series of analytic and comp
al steps, relating to the fluid transport, t
distribution, and the concentrations of the
chemical in the water and the bed. The m
been applied to analyze the temporal an
distribution of Kepone in the James Rive
both constant and time-variable freshwa
conditions. Using actual hydrology and
sumed mass rate of input of Kepone, the
tration was calculated for a 10-yr period
duction, comparing well to observed valu
water and bed. Projections are presented
mate the mass contained in the bed and
charged to Chesapeake Bay. (Author's

INTERACTION BETWEEN CO-SOLVENTS AND ALGAE IN THE RESIDUE DYNAMICS OF FENITROTHION,
Ottawa Univ. (Ontario). Dept. of Biology.
P. Weinberger, D. Sher, and R. Greenhalgh.
Journal of Environmental Sciences and Health, Vol. B18, No. 2, p 269-281, April, 1983. 4 Fig, 1 Tab, 8 Ref.

Descriptors: *Algae, *Pesticide residues, *Fate of pollutants, Fenitrothion, Bioaccumulation, Chlorophyta, Biodegradation, Solvents.

The specificity of pesticide effects coupled with high rates of pesticide accumulation noted for a range of genera of green algae have been explained as a function of passive partitioning of lipophylic xenobiotics into the lipid pools of the exposed organisms. This study was undertaken to determine whether this totally passive role for the aquatic phytobiota was correct. Fresh and estuarine water algae maintained in laboratory microcosms simulating river-lake/estuary-bay systems were exposed to C14-fenitrothion formulated with Atlox and tank mixed with Aerotex or Dowanol (11.5:1.5:15.5 w/v/v). Generally, the tank mix co-solvents determined the amount of uptake and the array of derivatives formed by the algae. Typically, exposed to an Aerotex mix the ratio of ethyl acetate extractable (NP) fraction : ethyl acetate unextractable (P) fraction was as 3.5:1.0, exposed to a Dowanol mix the ratio was as 1.5:1.0. Within any comparable time period, fresh water algae turned over more of the C14-ring of fenitrothion than the estuarine genera. Turn-over was enhanced when Aerotex was the tank mix co-solvent. Differences in uptake, turn-over, and degradation indicate that algae should be regarded as active rather than passive sinks. (Moore-IVI)

FURTHER WATER SOLUBILITY DETERMINATIONS OF INSECTICIDAL COMPOUNDS,
Department of Agriculture, London (Ontario). Research Centre.
B. T. Bowman, and W. W. Sans.
Journal of Environmental Science and Health, Vol. B18, No. 2, p 221-227, April, 1983. 1 Tab, 14 Ref.

Descriptors: *Insecticides, *Fate of pollutants, *Solubility, Fenamiphos, Fenthion, Methidathion, Carbaryl, Carbophenothion, Aminocarb, Diazinon, Dicapthon, Pirimiphos-ethyl, Pirimiphos-methyl.

The aqueous solubility of 39 pesticides and related compounds was determined at 20 + or - 1.5 C. All samples were analyzed by gas-liquid chromatography. Fenamiphos, fenthion and methidathion had solubilities substantially less than those reported in the literature. Carbaryl and carbophenothion had conflicting literature values, of which one for each compound agreed reasonably well with present data. Aminocarb, diazinon, dicapthon, pirimiphos-ethyl and pirimiphos-methyl gave solubilities substantially greater than their reported literature values. It is hoped that these solubility values will be of use in predicting the environmental fate of insecticides. (McKeon-IVI)

In the 1981 water year, bulk precipitation was primarily a solution of dilute H2SO4, and SO4(2-) was the dominant anion in throughfall and soil leachates in two eastern Tennessee deciduous forests. Ecosystems inputs of SO4(2-), which included dry deposition of forest canopies, may have been up to 40% greater than input estimates based on atmospheric deposition sampling in open areas. Volume- weighted mean annual pH of bulk precipitation was 4.3; of throughfall 4.8; and of leachates from O2, A1, and B21 soil horizons about 6.0. At both sites, strong acids in precipitation were largely neutralized prior to rainwater's infiltration into mineral soil. Base cations that exchanged with H(+) (hydrogen ions) in acid precipitation were almost entirely supplied by forest canopies and litter layers, and did not come directly from exchangeable mineral soil pools. However, even in these infertile soils with low cation exchange capacities, exchangeable bases were more than two orders of magnitude greater than annual H(+) input in bulk precipitation, and represented a substantial reserve for base cations in canopies and litter layers that exchanged with H(+) in acid rain. Furthermore, inputs of H(+) from acid precipitation were equal to about 0.4% of the base cations that are biologically cycling and immediately available in these ecosystems. Both soils are base-poor Udults and classified as sensitive to acid rain, but the deposition, cycling, and soil data presented in this report indicate that leaching remains a process affecting cation reserves and soil development only over the very long term. Published data on the fate of N15-labeled fertilizer applied to 4 Coshocton, Ohio, monolith lysimeters showed a series of declining NO3(-) - N concentration maxima in the lysimeter percolate during 3 winter drainage periods subsequent to the single 336 kg/ha fertilizer application. A possible explanation of these concentration maxima as arising from the leaching of previously immobilized and subsequently mineralized N was quantitatively inadequate. In this study, an alternative explanation of these observations was sought. The lowest meter in the 2.44-m deep monolith profile of Keene silt loam consisted of fissured shale bedrock, and analysis of mass conservation of N15-labeled inor-

ganic N in the fissured layer provided an explanation of these observed annually periodic concentration maxima. Some of the calculated flux of labeled N into the top of the fissured layer was shown to be stored within the layer, and to reappear in subsequent annual winter drainage periods. Two possible mechanisms, which allowed such temporary storage, were identified: storage within the pore space of the crack system, and storage in micropores of the weathered rock by lateral diffusion from solution contained in the cracks. ADSORPTION OF DIURON AND 2,4,5-T ON SOIL PARTICLE-SIZE SEPARATES,
Florida Univ., Gainesville. Dept. of Soil Science.
P. Nkedi-Kizza, P. S. C. Rao, and J. W. Johnson.
Journal of Environmental Quality, Vol. 12, No. 2, p 195-197, April-June, 1983. 3 Fig, 2 Tab, 15 Ref. R-805529.

Descriptors: *Herbicides, *Adsorption, *Particle size, Soil contamination, Diuron, Sediments, Non-point pollution sources, Path of pollutants, Organic carbon, Agricultural runoff.

Adsorption is a major process that influences the environmental fate and transport of pesticides in soil-water systems. A major pathway for pesticide removal from croplands is via runoff. During a runoff event, the clay-size and silt-size fractions are selectively carried off the field along with the runoff water. Equilibrium isotherms for the adsorption of herbicides, diuron, and 2,4,5-T on whole soil and various-size separates of Webster soil (Typic Haplaquolls) were measured. The Freundlich adsorption coefficient, K, for diuron varied by a factor of about 7 among the different particle-size fractions. However, the sorption coefficient, K, normalized with respect to soil organic carbon (OC) content, denoted as Koc = (K/OC), varied only within a factor of 1.5. For 2,4,5-T herbicide, the Koc values for the silt and clay-size fractions, as well as the whole soil, were essentially identical and about 3 times larger than that for the sand-size fraction. The results suggested that the soil particle- size separates may be grouped into two size classes: 'fine' (< 50 micro m) and 'coarse' (2,000-50 micro m). For a given pesticide, a specific Koc value may be assigned to each class. (Moore-IVI)

RESPONSE OF SPRUCE AND BIRCH FOLIAGE TO LEACHING BY ACIDIC MISTS,
Vermont Agricultural Experiment Station, Burlington.
T. Scherbatskoy, and R. M. Klein.
Journal of Environmental Quality, Vol. 12, No. 2, p 189-195, April-June, 1983. 2 Fig, 2 Tab, 34 Ref.

Descriptors: *Acid rain, *Leaching, *Throughfall, Cycling nutrients, Metabolites, Precipitation, Birch, Spruce, Trees.

Seedlings of yellow birch (Betula alleghaniensis Britt.) and white spruce (Picea glauca (Moench) Voss) were exposed to mists consisting of distilled water at pH 5.7, or sulfuric acid in distilled water at pH 4.3 or 2.8. Misting treatments, 4 h each, were applied once, twice or three times, separated by 72 h. Leaf tissue chlorophyll concentrations were determined, and foliar leachate was analyzed for K(+), Ca(2+), NO3(-), H2PO4(-), total carbohydrate, total protein, and total amino acids. Decreased leaching of carbohydrate, protein, K(+), and H2PO4(-) occurred with increasing number of mistings, indicating that these substances were not readily resupplied to leaching sites. Protein leaching was reduced by misting at pH 2.8. Leaching of amino acids, K(+), and Ca(2+) increased with decreasing mist pH, and leachate pH was higher than the pH of applied mists, suggesting that cation exchange plays a role in foliar leaching by acidic solution. Amino acid leaching from birch increased with increasing number of mistings at pH 2.8. There was no strong effect on chlorophyll concentrations, and leaching of NO3(-) and H2PO4(-) did not vary with mist pH. (Author's abstract)

CONTINUED STUDIES OF ACID RAIN AND ITS EFFECTS ON THE BATON ROUGE AREA,
Louisiana State Univ., Baton Rouge. Dept. of Chemistry.
J. W. Robinson, and H. Ghane.
Journal of Environmental Science and Health, Vol. A18, No. 2, p 165-174, 1983. 7 Fig, 1 Tab, 7 Ref.

Descriptors: *Acid rain, *Water pollution effects, Baton Rouge, Louisiana, Surface drainage, Wind, Water pollution sources, Dissolved oxygen, Seasonal variation, Lakes, Rainfall.

The acidity of rain water was measured in the Baton Rouge, Louisiana area from June 1981 to September 1982. Coordinated measurements were taken of the dissolved oxygen concentration in two local lakes before and after each rainfall. About 50% of the rainfall observed was quite acidic, with about 25% of the rain having a pH of 4 or less. Rain was more acidic during warm summers than in the winter weather. Rainfall during 1982 was, on a month to month comparison, more acidic than in 1981. Attempts were also made to discover any possible correlation of pH values with wind direction. The acidity of each of the two lakes increased over the time of the study. The dissolved oxygen content in each lake increased after periods of rain, probably due to a high concentration of oxygen in the rainwater. The buffering capacities of the lakes was measurable. However, it is noted that the larger lake was undergoing dredging at the time of the study and showed considerably less buffer capacity than the smaller lake. The smaller lake was far more affected by surface drainage and thus should have been more influenced by the acid rain. (Baker-IVI)

ASSESSMENT OF THE CHEMICAL AND BIOLOGICAL SIGNIFICANCE OF ARSENICAL COMPOUNDS IN A HEAVILY CONTAMINATED WATERSHED PART II. ANALYSIS AND DISTRIBUTION OF SEVERAL ARSENICAL SPECIES,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Environmental Science.
S. D. Faust, A. Winka, T. Belton, and R. Tucker.
Journal of Environmental Sciences and Health, Vol. A18, No. 3, p 389-411, 1983. 3 Fig, 6 Tab, 10 Ref.

Descriptors: *Arsenic compounds, *Water pollution sources, Union Lake, New Jersey, Sediment contamination, Chemical analysis, Pore water, Monomethlyarsonic acid, Dimethlyarsinic acid, Industrial wastes.

The waters and bottom sediments in the watershed of Union Lake in southern New Jersey are highly contaminated with substantial quantities of arsenic. The single source of this contamination is an industrial manufacturer of arsenical compounds in the headwaters of this watershed. Total arsenic contents were as high as 2780 micro g/1 in the water phase, whereas 2290 micro g/1 was the highest observed in bottom sediments. Pore water from this bottom sediment was 12,500 micro g/1. Arsenic contents in the bottom sediments were 4240 times those found in overlying waters. In sediments, the order of predominance of the four arsenic species was: As(+5) > As(+3) > monomethylarsonic acid (MMAA) > dimethylarsinic acid (DMAA). In four of the sediments, the inorganic arsenate was 72.8, 81, 84, and 88% of the total arsenical species. In water, the order of predominance was MMAA > As(+3), As(+5) > DMAA. Difficulties with the analytical procedure for separation of the four arsenical species include erratic recoveries of the four arsenical species from the cation exchange column, and difficulties in the separation of As(+3) and As(+5). Humic substances are widely distributed in the enviroment and have been known to enhance the photochemical degradation of synthetic organics in the aquatic environment. Naturally occurring fulvic acid (FA) is found to enhance the biodegradation of synthetic organics in experiments using 2-(methlythio)benzothiazole (MMBT) as an model contaminant. The FA was extracted from water of the Grand River, Ontario. For use as the inoculum, a MMBT degrading bacterial culture was derived from the activated sludge of a sewage treatment plant receiving wastewater from a firm manufacturing chemicals for the rubber industry. The ability of FA to stimulate biodegradation was clearly demonstrated. MMBT was degraded faster in a fermentor containing FA (half-life 60 hr) than in one without FA addition (half-life 104 hr). Since a large portion of dissolved organic matter in fresh water is present as fulvic acid, this enhanced biodegradation may play an important role in determining the fate of aquatic contaminants. Descriptors: *Sulfur, *Acid rain, *Sediments, Water pollution sources, Lake acidification, Sulfur isotopes, History, Ontario.

Sulfur pollution has closely been linked to the problems of acid precipitation and lake acidification. Although variations in sulfur isotypes can in principle be used to fingerprint the sources of sulfur in the lacustrine environment no attempt has so far been made to apply the technique in the study of pollutant sulfur in lakes in an historical sense. The concentrations and isotopic composition of sulfur in sediments of several softwater lakes of northern Ontario are reported. Lakes in the first group are located near Sudbury and are expected to derive most of their sulfur from the big nickel-copper smelter nearby. The second group of lakes are located in the more remote Algonquin Provincial Park with no know major local sources of sulfur. The sensitivity of the sediments to the influx of sulfur from local or distant sources is clearly demonstrated. (Moore-IVI)

BIOCONCENTRATION AND FIELD DISSIPATION OF THE AQUATIC HERBICIDE FLURIDONE AND ITS DEGRADATION PRODUCTS IN AQUATIC ENVIRONMENTS,
Lilly (Eli) and Co., Indianapolis, IN. Lilly Research Lab.
S. D. West, R. O. Burger, G. M. Poole, and D. H. Mowrey.
Journal of Agricultural and Food Chemistry, Vol. 31, No. 3, p 579-585, May/June, 1983. 12 Tab, 20 Ref.

Descriptors: *Biological magnification, *Fluridone, *Biodegradation, Herbicides, Fish, Pesticide residues, Aquatic environment, Hydrosoil, Aquatic weed control, Mathematical models.

The accumulation and dissipation patterns of the aquatic herbicide fluridone, 1-methyl-3-phenyl-5-(3-(trifluoromethyl)phenyl)-4(1H)-pyridinone, and its major degradation products have been determined in 40 pond and lake experiments in the United States, Panama, and Canada. The average bioconcentration factor for the total residue of fluridone plus a single major metabolite, 1-methyl-3-(4-hydroxyphenyl)-5-(3-trifluoromethyl)phenyl)-4(1H)-pyridinone, in several fish species was 1.33, 7.38, and 6.08 in edible tissue, inedible tissue, and whole body, respectively. Fluridone dissipated with an average half-life of 20 days in pond water and 3 months in pond hydrosoil. The treatment of small areas (0.8-4.0 ha) of large lakes resulted in more rapid dissipation due to dispersal of fluridone into the surrounding untreated water. Little or no carry-over of residues occurred prior to annual retreatments of the ponds. Mathematical models were evaluated for relating the half-life of fluridone in pond water to physical and chemical properties of the water. (Author's abstract)

BIOACCUMULATION OF ARSENIC BY FRESHWATER ALGAE AND THE APPLICATION TO THE REMOVAL OF INORGANIC ARSENIC FROM AN AQUEOUS PHASE. PART I. SCREENING OF FRESHWATER ALGAE HAVING HIGH RESISTANCE TO INORGANIC ARSENIC,
Kagoshima Univ. (Japan). Dept. of Applied Chemistry.
S. Maeda, T. Kumamoto, M. Yonemoto, S. Nakajima, and T. Takeshita.
Separation Science and Technology, Vol. 18, No. 4, p 375-385, 1983. 4 Fig, 4 Tab, 11 Ref.

Descriptors: *Algae, *Arsenic, *Fate of pollutants, *Bioaccumulation, Chlorella, Diatoms, Cyanophyta, Chlorophyta, Protozoa, Rotifers, Bacteria, Mine wastes, Geothermal power, Effluent.

Several freshwater alga having resistance to arsenic were screened from microorganisms which had been sampled at sites polluted with arsenic from a geothermal electric power plant and old mines and smelters and arsenic ores. The alga thus screened could grow in the liquid medium (Modified-Detmer culture medium) containing sodium arsenate at levels up to 2000 ppm as elemental arsenic concentration. Some mixed systems of alga grew rapidly in the media at the higher levels of arsenic ranging from 50 to 2000 ppm. The mixed systems of alga screened included predominantly blue-green algae, green algae, and diatoms, and also included protozoa, rotifera, and bacteria as minor components. One pure algal culture was obtained by means of an agar plate culture, and the algae isolated was identified as Chlorella vulgaris Beijerinck var. vulgaris. The growth of C. vulgaris in a pure culture was unaffected by 100 ppm of arsenic. (Author's abstract)

SEASONAL VARIATIONS OF CD, PB, CU AND NI LEVELS IN SNOW FROM THE EASTERN ARCTIC OCEAN,
Kernforschungsanlage Juelich G.m.b.H. (Germany, F.R.). Inst. fuer Chemie.
L. Mart.
Tellus, Vol. 35B, No. 2, p 131-141, April, 1983. 1 Fig, 8 Tab, 37 Ref.

Descriptors: *Snow, *Heavy metals, *Arctic, Lead, Cadmium, Copper, Nickel, Cobalt, Seasonal variation, Air pollution.

During the Swedish Arctic expedition 'Ymer 80' into the area from North Greenland to Franz-Josef-Land in late summer 1980, freshly fallen snow, and snow from the previous fall/winter season were collected from ice floes. Lead, cadmium and copper analysis was performed on board ship, using the advanced voltammetric determination method of differential pulse anodic stripping voltammetry at rotating glassy carbon electrodes. The analytic operations were performed under a clean bench in a clean room container. Nickel, and tentatively, cobalt levels were analyzed in the home laboratory by differential pulse voltammetry after preconcentration by chelate adsorption at a hanging mercury drop electrode. Results from freshly fallen snow compared to snow from the previous season show that there exists a strong seasonal variation in trace metal deposition, indicating that pollution of the Arctic atmosphere is clearly limited to winter time, when atmospheric conditions favor long-distance transport of polluted air masses from Europe to the Arctic. Unexpectedly low mean levels of 0.4 ng/kg Cd, 13 ng/

kg Pb, 20 ng/kg Cu and 22 ng/kg Ni were found in freshly fallen snow, levels that represent about 1/10 to 1/20 of those in annual condensed layers. (Author's abstract)

SIMULATION OF SOLUTE TRANSPORT IN A CHEMICALLY REACTIVE HETEROGENEOUS SYSTEM: MODEL DEVELOPMENT AND APPLICATION,
California Univ., Berkeley. Lawrence Berkeley Lab.
C. W. Miller, and L. V. Benson.
Water Resources Research, Vol. 19, No. 2, p 381-391, April, 1983. 8 Fig, 2 Tab, 24 Ref. DEAC03-76SF00098, DOE 50-80-97.

Descriptors: *Solute transport, *Route of pollutants, Advection, Diffusion, Mathematical models, Ion exchange, Mass action, Water dissociation, Strontium, Groundwater pollution, Aqueous complexation.

One-dimensional transport of solutes in a saturated porous medium has been simulated using a numerical model CHEMTRN. This model includes dispersion/diffusion, advection, ion exchange, formation of complexes in the aqueous phase, and the dissociation of water. The mass action, transport, and site constraint equations are expressed in a differential/algebraic form and solved simultaneously. In the mass action equations describing complexation and sorption processes, the activities of the species in the aqueous phase are approximated using the Davies equation. A solubility constraint can be set at the inner boundary. The model was applied to a study of the migration of strontium in groundwater. Results show that surface site competition is important when the strontium concentration is comparable to the background electrolyte concentration, in which case a constant k sub D model does not simulate the transport of chemical species adequately. In addition, the pH level was buffered to a level of approximately 10 near the wasteform due to the incorporation of the solubility constraint. For the particular case studied, the incorporation of aqueous complexation did not significantly enhance strontium mobility. (Author's abstract)

COMBINED MIXING CELL/ANALYTICAL MODEL TO DESCRIBE TWO-DIMENSIONAL REACTIVE SOLUTE TRANSPORT FOR UNIDIRECTIONAL GROUNDWATER FLOW,
Kiel Univ. (Germany, F.R.). Geologisch-Palaeontologisches Inst. und Museum.
H. D. Schulz, and E. J. Reardon.
Water Resources Research, Vol. 19, No. 2, p 493-502, April, 1983. 7 Fig, 1 Tab, 8 Ref.

Descriptors: *Groundwater movement, *Solute transport, Mathematical models, Mixing, Ion exchange, Chemical precipitation, Advection, Dispersion, Calcite, Path of pollutants.

A combined two-dimensional mixing cell/analytical solution is presented which describes multiple reactive solute transport in unidirectional groundwater flow regimes. The model uses a two-step solving routine which separates chemical equilibria computations (ion exchange and mineral precipitation/ dissolution) from calculations of advection/ dispersion. Before running the model for a particular grid configuration, an isochemical flow situation is run first to calibrate the model. The calibration technique adjusts for mass losses or gains to and from cells, which occurs when using mixing cell models. Computational time for calculating chemical equilibria in each mixing cell is markedly reduced by the use of a single-equation solution to solve for multi-ion exchange equilibria and a rapid iterative technique to solve for calcite equilibria. The application of the model to simulate a solution injection experiment into an unconsolidated sand deposit yielded results in reasonable agreement with field observations. (Author's abstract)

EFFECTS OF LIGHT AND THE IMPORTANCE OF LIVING PLANT TISSUES ON THE FATE OF (14C)PHORATE IN WATER AND ELODEA PLANTS,
Wisconsin Univ.-Madison. Dept. of Entomology.
G. Walter-Echols, and E. P. Lichtenstein.
Journal of Agricultural and Food Chemistry, Vol. 31, No. 3, p 637-641, May/June, 1983. 4 Fig, 1 Tab, 11 Ref.

Descriptors: *Pesticide residues, *Light effects, *Elodea, Vegetation, Plant physiology, Carbon radioisotopes, Insecticides, Metabolism, Water pollution effects.

The importance of living plant tissues and light on the uptake and metabolism of C-14 phorate-derived residues from water by Elodea nuttallii plants was investigated. Plants growing for 2 weeks in water with a bottom deposit of C-14 phorate-treated soil accumulated in their tissues up to 30% of the originally soil-applied radiocarbon and 56% when the insecticide had been directly applied to the water. Most of the C-14 labeled compounds thus taken up were bound to plant tissues, which might explain the small amounts of radiocarbon released later from these plants into insecticide-free water. The uptake of insecticides from water was a function of the living plant, since dead plant tissues contained only small amounts (2.6% of that found in living plants) of C-14 labeled compounds after having been exposed for 72 h to C-14 phorate-contaminated water. Moreover, most of the C-14 phorate-derived compounds (38.4% of applied) were taken up by Elodea plants when exposed to light, while plants incubated in the dark contained only 9% of the radiocarbon originally applied to the water. BEHAVIOUR OF COPPER, ZINC, IRON AND MANGANESE DURING EXPERIMENTAL RESUSPENSION AND REOXIDATION OF POLLUTED ANOXIC SEDIMENTS,
Lancaster Univ., Bailrigg (England). Dept. of Environmental Sciences.
J. M. Hirst, and S. R. Aston.
Journal of Estuarine, Coastal and Shelf Science, Vol. 16, No. 5, p 549-558, May, 1983. 3 Fig, 4 Tab, 11 Ref.

Descriptors: *Suspended sediments, *Estuarine environment, *Water pollution, *Metals, Resuspension, Oxidation, Copper, Zinc, Iron, Manganese, Water temperature, Salinity, Hydrogen ion concentration, Oxygen concentration, Path of pollutants.

Samples of anoxic intertidal sediments from the Mersey Estuary, north-west England, have been used in laboratory experiments to determine the rates and extents of metal (Cu, Zn, Fe, Mn) releases to solution under conditions of controlled resuspension and reoxidation. An experimental system for the study of sediment-water interactions at various temperatures, salinities, pHs and oxygen concentrations is described. The results indicate rapid initial losses of Fe and Mn from sediment but not Cu and Zn with longer term readsorption of Fe and Mn to give partitioning between the aqueous/sediment phases for all four metals which is similar to that under the initial anoxic conditions. Cu and Zn show small, but measurable, net losses from the aqueous phase to the reoxidized sediment. Salinity variations exert little influence on the processes observed, but increasing temperature produces increased Cu, Zn and Mn in the dissolved fraction at equilibrium conditions. Exchan Cu and Zn between the sediment/water pha rather insensitive to pH or oxygen concentr but Fe and Mn do respond to increasing pH suppress their initial release on oxidation. oxygen concentrations can result in a slo significant release of Fe. In relation to trace pollution in estuaries and biological avail the results suggest that the resuspension and tion of polluted anoxic sediments is not an i tant process because of scavenging of metals on to the resuspended material. SURVIVAL OF NATURAL SEWAGE POP TIONS OF ENTERIC BACTERIA IN DI SION AND BATCH CHAMBERS IN MARINE ENVIRONMENT,
Rhode Island Univ., Kingston. Dept. of Mic ology.
E. J. Lessard, and J. M. Sieburth.
Applied and Environmental Microbiology, 45, No. 3, p 950-959, March 1983. 6 Fig, 1 Ta Ref. EPA grants R804866010 and R80486 NSF grant OCE-7681779.

Descriptors: *Escherichia coli, *Estuarine env ment, *Salt marshes, *Enteric bacteria, Se bacteria, Wastewater pollution, Temperatur fects, Light effects, Rhode Island, Narraga Bay, Bisset Cove.

The survival of natural populations of Escher coli and enterococci in sewage was measure large-volume diffusion chambers in an estuary a salt marsh. The 5-liter chambers, with poly bonate membrane sidewalls, were found to be able for up to week-long experiments. Decay measured monthly from February to August ranged from 0.042 to 0.088/hr (time for 90% o population to die = 25 to 55 hr) for E. coli 0.019 to 0.083/hr (time for 90% of the popul to die = 29 to 122 hr) for enterococci and significantly correlated with temperature. In trast to the diffusion culture experiments, decay of E. coli in batch culture did not corr with temperature. Enterococci survived lo than E. coli in the Narragansett Bay (estu experiments, but survived less well in the eutrophic salt marsh. The effect of light on sur al was examined with light/dark experiments sampling at frequent intervals over the diel c Diel changes in survival were not evident in Narragansett Bay experiments. E. coli, howe

d a diel pattern of growth during the day
th at night in the salt marsh. There was no
nt difference in decay rates between light
k diffusion chambers, nor were decay rates
ed with light intensity. In concurrent batch
ents, survival was significantly greater in
for both organisms. These results suggest
effect of light is complex and that condi-
batch culture may modify the survival of
bacteria. Observations made in diffusion
rs may more closely follow the in situ
of enteric microorganisms. (Author's ab-

PHYSIOLOGICAL CHANGES IN CARPS INDUCED BY POLLUTION,
Karlsruhe Univ. (Germany, F.R.). Dept. of Zoology II.
W. Hanke, G. Gluth, H. Bubel, and R. Muller.
Ecotoxicology and Environmental Safety, Vol. 7, No. 2, p 229-241, April, 1983. 9 Fig, 27 Ref.

Descriptors: *Pesticides, *Carp, *Toxicity, *Bioassay, *Enzymes, Indicators, Bioindicators, Cortisol, Glucose, Glycogen, Atrizine, Insecticides, Fungicides, Herbicides.

Physiological changes in carp were evaluated for use as indicators of pollutants in environmental water systems. The pesticide DDT, the herbicide atrazine, the fungicides PCP and HCB, and the insecticides dieldrin, lindane and aldrin were used as test pollutants. The pollutants induce changes in cortisol and glucose levels in serum, variations in the amount of liver glycogen and liver function, changes in gill ATPase and brain and serum acetylcholinesterase of carp. There is always a biphasic response, with an increase in the concentration or enzyme activity for a short time, and a decrease or inhibition of the enzymes after a longer exposure to the pollutants. The time scale (the duration of the periods of increase and decrease) depends on the concentration and toxicity of the pollutants. Comparison of carp in fresh water and carp acclimated to 1.2% salt water indicates that there is greater sensitive to the pollutants under the influence of salt water. All responses are unspecific. Suggestions are given for the use of these tests as criteria for water quality. (Moore-IVI)

EFFECTS OF TEMPERATURE AND COLOR COMPONENTS OF WASTEWATER DISCHARGES ON AQUATIC COMMUNITIES,
Westvaco Corp., Covington, VA.
T. G. Botkins, Jr.
Tappi Journal, Vol. 66, No. 3, p 107-110, March, 1983. 5 Fig, 1 Tab.

Descriptors: *Thermal pollution, *Color, *Pulp wastes, Water pollution effects, Effluents, Industrial wastes, Aquatic life, Simulation, Model studies, Cooling water, Stream discharge, Fish, Bass, Jackson River, Virginia.

Westvaco operates a bleached kraft and semi-chemical pulp and paper mill and an activated carbon plant in Covington, Virginia. Process and cooling-water effluents from the facility are discharged into the Jackson River. A thermal discharge demonstration was conducted to evaluate the effects of temperature and color components of the discharges on aquatic communities. The study included: modeling to simulate stream flows and temperatures, an evaluation of the thermal tolerance limits of fish and supportive tropic levels, and the execution of bioassays to assess the joint effect of temperature and color on smallmouth bass. It was concluded that mill effluents would not cause an imbalance of the indigenous aquatic communities. (Moore-IVI)

SORPTION OF POLYCHLORINATED BIPHENYLS (PCB) TO CLAY PARTICULATES AND EFFECTS OF DESORPTION ON PHYTOPLANKTON,
State Univ. of New York at Stony Brook. Marine Sciences Research Center.
G. M. Nau-Ritter, and C. F. Wurster.
Water Research, Vol. 17, No. 4. p 383-387, April, 1983. 5 Fig, 1 Tab, 27 Ref.

Descriptors: *Polychlorinated biphenyls, *Clays, *Sorption, *Phytoplankton, Illite, Chlorite, Water pollution effects.

The sorption of polychlorinated biphenyls (PCB) on illite and chlorite, two minerals of defined comparison, was investigated. Illite particles adsorbed higher C-14 PCB (Aroclor 1254) concentrations than did chlorite particles with equilibrium concentration factors between particles and water being 1.4 x 0.0001 for illite and 1.0 x 0.0001 for chlorite. Desorbed PCB inhibited photosynthesis and reduced chlorophyll-a content of natural phytoplankton assemblages within dialysis membrane bags suspended in the water of a tidal marsh. There was no significant difference in effects on the phytoplankton of PCB desorbed from the two minerals. The rate of C-14 PCB desorption was dependent on the initial concentration on the clay particles. The rate of C-14 PCB loss from bags with particles was slower than that from bags without particles. (Author's abstract)

THE INFLUENCE OF SPRING AND FALL TEMPERATURES ON THE AVOIDANCE RESPONSE OF JUVENILE ATLANTIC MENHADEN, BREVOORTIA TYRANNUS, EXPOSED TO SIMULTANEOUS CHLORINE-DELTA T CONDITIONS,
Johns Hopkins Univ., Laurel, MD. Applied Physics Lab.
L. W. Hall Jr., D. T. Burton, S. T. Margrey, and W. C. Graves.
Water Resources Bulletin, Vol. 19, No. 2, p 283-287, April, 1983. 2 Fig, 2 Tab, 25 Ref.

Descriptors: *Power plants, *Menhaden, *Chlorine, *Temperature effects, Fish behavior, Avoidance, Environmental effects, Chlorination, Cooling water, Effluent, Residual chlorine, Acclimation.

The avoidance response of groups of juvenile Atlantic menhaden, Brevoortia tyrannus, was evaluated by exposing test species to a range of simultaneous total residual chlorine (TRC) (0.00, 0.05, 0.10, and 0.15 mg/L) and elevated temperature (0, 2, 4, and 6 C) conditions simulating power plant discharges. This species was tested at both 15 and 20 C to determine possible effects of acclimation temperature on the avoidance response. These temperatures were selected to represent spring or fall thermal conditions when most East Coast power plant facilities initiate power plant chlorination in the spring or terminate the use of this biocide in the fall. An unbalanced 3-factor factorial design was used to develop response surface avoidance models at 15 and 20 C. The model developed at 15 C showed: (1) an increase in avoidance occurred at all delta T conditions as TRC increased from 0.00 to 0.05 mg/L; (2) a greater degree of avoidance occurred at TRC concentrations above 0.05 mg/L at all delta T conditions; and (3) TRC was the most important term influencing avoidance. There was a significant difference ($p<0.00001$) between avoidance models at 15 and 20 C. However, when extreme conditions of 0.15 mg/L TRC and 0-6 C T were compared, the degree of avoidance responses (percent time in control area) was similar. (Author's abstract)

DISSIPATION OF 2,4-D DMA AND BEE FROM WATER, MUD AND FISH AT LAKE SEMINOLE, GEORGIA,
Army Engineer Waterways Experiment Station, Vicksburg, MS. Environmental Lab.
R. E. Hoeppel, and H. E. Westerdahl.
Water Resources Bulletin, Vol. 19, No. 2, p 197-204, April, 1983. 2 Fig, 2 Tab, 42 Ref.

Descriptors: *Dissolved oxygen, *Herbicides, *Water pollution effects, Pesticides, Acidity, Lakes, 2,4-D, Lake Seminole, Georgia, Myriophyllum.

Dense watermilfoil beds of Lake Seminole, Georgia were treated with either 2,4-D dimethylamine (DMA) or 2,4-D bisoxyethanol ester (BEE) at rates of 22.5 and 45 kg a.e./ha. Rapid conversion of both formulations to the 2,4-D acid form was observed with no detection of either original compound in the water in less than 24 hrs after application. Maximum detected 2,4-D concentrations in the high rate, 2,4-D DMA and 2,4-D BEE plots were 3.6 and 0.68 mg/l, respectively. All but seven samples at a 2,4-D BEE plot showed non-detectable herbicide levels after 6 days and all water samples were below detectable limits by day 13. Potentially toxic transformation products such as dimethylnitrosamine and 2,4-dichlorophenol were not detected. No significant accumulation of 2,4-D was found in fish collected from sites treated with 2,4-D DMA. Sedimentation showed no significant accumulation of 2,4-D, 2,4-D BEE or 2,4-dichlorophenol. Small decreases in dissolved oxygen and pH, associated with the complete watermilfoil control in plots had returned to normal summer values by day 28. (Baker-IVI)

TOTAL MERCURY IN FISHES AND SELECTED BIOTA IN LAHONTAN RESERVOIR, NEVADA: 1981,
Nevada Univ. System, Reno. Bioresources Center.
J. J. Cooper.
Bulletin of Environmental Contamination and Toxicology, Vol. 31, No. 1, p 9-17, July, 1983. 3 Tab, 27 Ref. 14-34-0001-0271.

Descriptors: *Mercury, *Fish, *Biological magnification, Water pollution effects, Industrial wastes, Heavy metals, Bioaccumulation, Lahontan Reservoir, Nevada.

Lahontan Reservoir, located 72 km southeast of Reno, Nevada, receives the entire flow of the Carson River. Mercury was introduced into the Carson River during the mining of gold and silver in the Comstock Lode. During the summer of 1981 fish were collected for analysis using a variety of methods including gill netting, beach seining and dip netting. Results of cold vapor atomic absorption analysis indicate that significant mercury accumulation is occurring within fishes of Lahotan Reservoir. Mercury concentrations in muscle tissue collected from 11 species ranged from 0.11 mg/kg in young-of-the-year white bass to 9.52 mg/kg in a striped bass with a know residence time within the waterbody of 16 yr. Of 53 muscle tissue samples analyzed, 36 (68%) exceeded the 1 mg/kg action level. In general, mercury concentrations within species increased with fish weight. A significant difference was found between mean mercury concentration in omnivores (1.16 mg/kg) compared to second order piscivores (1.64 mg/kg) ($P<0.05$). Likewise, mean mercury concentrations of the second order piscivores were significantly lower than first order piscivores (3.39 mg/kg) ($P<0.001$). This suggests that biomagnification is occurring within the fishes of Lahontan Reservoir. (Moore-IVI)

EFFECTS OF TEMEPHOS ON THE RESPIRATORY RATE OF THE SALT MARSH AMPHIPOD, GAMMARUS MUCRONATUS,
Northeastern Univ., Boston, MA. Dept. of Biology.
E. Ruber, and K. LaFrance.
Bulletin of Enviromental Contamination and Toxicology, Vol. 31, No. 2, p 148-151, August, 1983. 1 Fig, 2 Tab, 6 Ref. RR07143.

Descriptors: *Toxicity, *Insecticides, Temephos, Amphipods, Environmental effects, Aquatic animals.

In order to determine whether overall changes in metabolic rate of amphipods can be detected at sublethal concentrations of insecticides and whether this could lead to predictions of mortality after 48-hr or longer, the amphipod Gammarus mucronatus was exposed to the organophosphate temephos. After exposure, the gammarids were removed to vials where oxygen concentration changes over 4-hr were measured. The reduction in oxygen concentration after exposure to 0.01 ppm temephos is not statistically significant, but the reduction after exposure to 0.1 ppm is. This shows significant respiratory inhibition at 24-hr at concentrations of insecticide which do not cause significant 24-hr mortality rates. With further refinements, this technique may be useful for impact analysis. (Moore-IVI)

CONCENTRATIONS OF UNSUBSTITUTED POLYCYCLIC AROMATIC HYDROCARBONS IN SOFTSHELL CLAMS FROM COOS BAY, OREGON, USA,
Oregon State Univ., Corvallis. Dept. of General Science.
M. C. Mix, and R. L. Schaffer.
Marine Pollution Bulletin, Vol. 14, No. 3, p 94-97, March, 1983. 2 Tab, 1 Fig. CR 808000-01-0.

Descriptors: *Polycyclic aromatic hydrocarbons, *Benzo(a)pyrene, *Clams, Monitoring, Water pollution, Estuaries, Hydrocarbons, Industrial plants, Bays, Oregon.

Concentrations of benzo(a)pyrene (BAP) were measured in subpopulations of softshell clams, Mya arenaria, from four intertidal sites in Coos Bay from June 1976 to June 1978. Subsequently, concentrations of 15 unsubstituted polynuclear aromatic hydrocarbons (PNAH) were determined in two subpopulations from September 1978 to August 1979. There were significant differences between BAP concentrations in clams from the four sites. For the two-year period, they were highest in clams inhabiting areas adjacent to the industrialized bayfront and lowest in clams inhabiting more remote areas. There were no significant seasonal variations in BAP concentrations during this period. During the 1978-79 study, the average total PNAH concentration in clams from the bayfront area was 555.1 microgram/kg compared to 76.3 microgram/kg for clams from a more remote environment. In general, PNAH concentrations were lowest in the fall-winter and highest during the spring-summer. It appears that the use of clams as indigenous monitors has significant merit, particularly in bays such as those in Oregon which are fresh-water dominated for extended periods of the year. The BAP and PNAH levels in clams from the four sites reflected the degree of development and industrialization and presumably, the level of contamination in the overlying water column. (Moore-IVI)

UPTAKE OF LEAD AND CHROMIUM BY PRIMARY PRODUCERS AND CONSUMERS IN A POLLUTED LAGOON,
Cagliari Univ. (Italy). Dept. of Pharmaceutical Chemistry and Toxicology.
W. Capone, C. Mascia, M. Porcu, and M. L. Tagliasacchi Masala.
Marine Pollution Bulletin, Vol. 14, No. 3, p 97-102, March, 1983. 3 Fig, 10 Tab, 6 Ref.

Descriptors: *Bioaccumulation, *Industrial wastes, *Lagoons, Water pollution effects, Petrochemicals, Oil industry, Crustaceans, Trophic levels, Sediments, Sardinia, Lead, Chromium.

Sediments, aquatic macrophytes and some species of crustacea taken from the S. Gilla lagoon in Sardinia were analyzed for possible concentrations of lead and chromium resulting from exposure to wastewater from urban centers and industrial plants and pollution from a nearby petrochemical plant. Among the Thallophyta tested, the highest values of bioaccumulation were found in Polysiphonia, which were totally absent from some sampling sites. In the Ruppia type a lead higher accumulation was noted in the radical apparatus and for chromium in the foliar one. The values of foliar bioconcentration for both metals do not change greatly with changes in the concentrations in the sediments. Among the Crustacea considered, the order of decreasing importance concerning bioconcentration for chromium and lead is Corpophium, Sphaeroma, Gammarus, and Idothea. The total lagoon mean values of transfer factors between the various crustacea and the seaweed which they usually consume show a tendency to acc
more chromium than lead. The exceptio
case of Sphaeroma could be explained
higher weight in its exoskeleton due to the
content. (Baker-IVI)

INFLUENCE OF SUBSTRATUM WETTABILITY ON ATTACHMENT OF FRESHWATER BACTERIA TO SOLID SURFACES,
Warwick Univ., Coventry (England). Dept. of Environmental Sciences.
J. H. Pringle, and M. Fletcher.
Applied and Environmental Microbiology, Vol. 45, No. 3, p 811-817, March 1983. 4 Fig, 3 Tab, 37 Ref.

Descriptors: *Bacteria, *Substrates, *Wettability, *Deterioration, Corrosion, Clogging, Adhesion, Wastewater treatment.

Attachment of bacteria to surfaces of flowing systems such as pipelines ensures that the population is not eliminated by washout and may be the first stage in the deterioration of such structures through corrosion or clogging. Bacterial adhesion and growth on various substrata can have advantages in biotechnological processes such as waste treatment. The attachment of a number of freshwater bacteria from River Sowe, Coventry, England, to hydrophobic and hydrophilic surfaces was evaluated, and further studies evaluated the attachment of selected isolates to a number of substrata with a range of water wettabilities. The wettability of each substratum was determined by contact angle measurement and was expressed as the work of adhesion. No generic pattern of attachment to the test surfaces was found, although the majority of the organisms isolated showed a preference for the hydrophobic surface. A more detailed study of selected isolates showed a relationship between the work of adhesion and number of attached cells. Each bacterium attached in maximum numbers to a surface that was characteristic of that organism and that had a work of adhesion between 74 and 105 mJ/sq m. (Moore-IVI)

CHLORINE-INDUCED DAMAGE TO SURFACE ADHESIONS DURING SUBLETHAL INJURY OF ENTEROTOXIGENIC ESCHERICHIA COLI,
West Virginia Univ., Morgantown. Div. of Plant and Soil Sciences.
S. M. Walsh, and G. K. Bissonnette.
Applied and Environmental Microbiology, Vol. 45, No. 3, p 1060-1065, March 1983. 2 Fig, 4 Tab, 36 Ref.

Descriptors: *Escherichia coli, *Chlorination, *Fecal coliforms, *Pathogenic bacteria, Bacterial analysis, Indicators, Public health, Infection, Wastewater treatment.

The assessment of the sanitary quality of water may be complicated by the presence of sublethally injured fecal indicator organisms. A portion of the viable population may escape detection by most methods prescribed for the bacteriological examination of water. A comparison of the adhesive ability of noninjured and chlorine-injured enterotoxigenic E. coli was made by in vitro attachment to human peripheral leukocytes. Chlorination selected for noninjured cells with greater capabilities for colonizing the small intestine. Injured populations exhibited reduced association with leukocytes. The maximum reduction was seen in populations with greater than 80% injury. These cells demonstrated less adhesive ability than nonpiliated populations. Electron micrographs suggested that reduced adhesive ability was due to the loss of surface structures as a consequence of sublethal chlorination. The data implied a reduced ability among chlorine-injured pathogens to colonize the small intestine and initiate disease. (Moore-IVI)

MICROBIAL FOULING OF REVERSE-OSMOSIS MEMBRANES USED IN ADVANCED WASTEWATER TREATMENT TECHNOLOGY: CHEMICAL, BACTERIOLOGICAL, AND ULTRASTRUCTURAL ANALYSES,
California Univ., Irvine. Environmental Analysis Div.
H. F. Ridgway, A. Kelly, C. Justice, and B. H. Olson.
Applied and Environmental Microbiology, Vol. 45, No. 3, p. 1066-1084, March 1983. 13 Fig, 3 Tab, 35 Ref. Orange Co. Water Dist. contract 4107-160-81.

Descriptors: *Reverse osmosis, *Membrane processes, *Bacteria, Advanced wastewater treatment, Cellulose acetate membranes, Acinetobacter, Flavobacterium, Moraxella, Pseudomonas, Alcaligenes, Bacillus, Lactobacillus, Wastewater treatment, California, Orange County, Water Factory 21.

Biofouling of reverse-osmosis membranes was investigated at an advanced wastewater treatment facility. Cellulose diacetate membranes operated for approximately 4,000 hr became uniformly coated with a mucilaginous fouling layer. The fouling material was approximately 93% water by weight, and nearly 90% of the dehydrated residue was organic in composition. Calcium, phosphorus, sulfur, and chlorine were the major inorganic constituents detected. Protein and carbohydrate represented as much as 30 and 17%, respectively, of the dry weight of the biofilm. Bacteriological plate counts indicated up to 5,600,000 colony forming units/sq cm of membrane surface. Accumulation of (H3)glucose in the biofilm and measurement of ATP indicated that the fouling bacteria were metabolically active in situ. The genus Acinetobacter and the Flavobacterium-Moraxella group were the major generic groups associated with the feed-water surface of the membrane, whereas species of the generic groups Acinetobacter, Pseudomonas-Alcaligenes, and Bacillus-Lactobacillus predominated of the permeate water surface. Electron microscopy revealed that the biofilm on the feed-water surface of the membrane was 10 to 20 millimicrons thick and was composed of several layers of compacted bacterial cells, many of which were partially or completely autolyzed. The bacteria were firmly attached to the membrane surface by an extensive network of extracellular polymeric fibrils. Polyester (Texlon) support fibers located on the permeate surface of the reverse osmosis membranes were sparsely colonized, suggesting bacterial regrowth in the product water collection system. PEROXIDASE-CATALYZED REMOVAL OF PHENOLS FROM COAL-CONVERSION WASTE WATERS,
Massachusetts Inst. of Tech., Cambridge. Dept. of Nutrition and Food Science.
A. M. Klibanov, T.-M. Tu, and K. P. Scott.
Science, Vol. 221, No. 4607, p 259-261, July, 1983. 1 Fig, 19 Ref.

Descriptors: *Wastewater treatment, *Phenols, *Enzymes, Horseradish peroxidase, Hydrogen peroxide, Coal gasification, Degradation.

An enzymatic approach is described for the removal of phenols from coal conversion aqueous effluents. Upon addition of horseradish peroxidase and hydrogen peroxide, a solution containing phenol immediately turns brown and a precipitate forms gradually, a response not brought on by the use of either reagent alone. Removal efficiencies of 99% can be obtained. The treatment was examined in the practical range of phenol concentrations of from 0.01 to 5 g/liter (pH 9). A typical coal gasification waste water was also examined as it was expected to contain constituents that would adversely affect bacterial and other methods of dephenolization. The sample included: phenol, 2 g/l; ammonia, 5 g/l; chloride, 19 g/l; cyanide, 0.1 g/l; thiocyanate, 1 g/l; and had a pH of 9.0. When 2 units of peroxidase per ml and 2 mM of H_2O_2 were added to a 0.1 g/l of the test solution a removal efficiency of only 10% was achieved. In the absence of these additional contaminants a 99% removal efficiency had been noted. However, increasing the concentration of phenol to 2 g/l and the concentrations of peroxidase and H_2O_2 proportionally, the removal efficiency jumped to 97% as compared to a 98% removal efficiency for 2 g/l

phenol in the absence of other contaminants. This indicated that at high, significant phenol concentrations, the presence of contaminants is not an important factor to the operation of this method. Other experiments showed that pollutants such as polychlorinated biphenyls can be enzymatically coprecipitated with the phenols. One possible use of this dephenolization method would be to replace conventional bacterial degradation of phenols in open ponds. This new method would be much less sensitive than bacterial degradation to variations in pH, phenol concentration, other toxic pollutants, and temperature. (Baker-IVI)

CHEMICAL CLARIFICATION OF DREDGED MATERIAL,
Army Engineer Waterways Experiment Station, Vicksburg, MS.
P. R. Schroeder, and F. D. Shields, Jr.
Journal of Environmental Engineering, Vol. 109, No. 2, p 414-427, April, 1983. 3 Fig, 2 Tab, 7 Ref.

Descriptors: *Clarification, *Wastewater treatment, *Dredged material, Effluent, Flocculation, Polymers, Costs, Containment area effluents, Sediments.

Dredged material may be disposed in diked containment areas instead of open water in order to reduce adverse impacts on the aquatic community and water quality and to allow productive use of the dewatered material. Laboratory and design procedures have been developed for chemical clarification of dredged material containment area effluents based on results of laboratory and field tests. The design is suitable for normal disposal operations including remote locations, high and variable flows and solids loadings, and temporary and intermittent operations. The treatment system requires minimal equipment and operations. Low viscosity, highly cationic liquid polymer is applied at the drainage structure of the primary containment cell. Mixing for dispersing polymer and flocculation is provided by turbulence of flow through the discharge culvert. A small secondary cell is used for settling and storage of treated material. Design parameters are determined by jar tests. Major cost components, are polymer, labor, and construction. The cost for equipment, labor, and polymer should range from $0.08/cu yd-0.25/cu yd ($0.10/cu m-0.33/cu m) (1981 dollars) of in situ sediment dredged and is dependent on the production rate, polymer dosage, and treatment system design. (Moore-IVI)

ANAEROBIC TREATMENT OF DILUTE WASTEWATERS USING AN UPFLOW SLUDGE BLANKET REACTOR,
Birmingham Univ. (England). Dept. of Civil Engineering.
C. F. Forster, and D. A. J. Wase.
Environmental Pollution (Series A), Vol. 31, No. 1, p 57-66, May, 1983. 3 Fig, 4 Tab, 17 Ref.

Descriptors: *Anaerobic digestion, *Upflow sludge blanket, *Industrial wastes, *Wastewater treatment, Food-processing wastes, Chemical wastes, Plug flow, Kinetics.

An anaerobic upflow sludge blanket (USB) reactor was used successfully to treat two effluents, a confectionery waste in which sugar was the main component, and a chemical waste of which the principle constituent was acetate, of much lower strengths than those hitherto reported as suitable for such a system. The confectionery waste was mixed with settled domestic sewage to achieve a predetermined strength, and nitrogen and phosphorus were added, in excess, to the acetate waste to ensure that these nutriments were not limiting. Analysis of the results indicated first-order kinetics and plug-flow characteristics within the reactor. Data for COD removal and gas yield showed that this system compared favorably with an anaerobic filter, and also suggested that the confectionery waste was in some way limited, or contained inhibitor, emphasizing a need for preliminary studies. CONFIRMED VIRUSES VERSUS UNCONFIRMED PLAQUES IN SEWAGE,
Metropolitan Sanitary District of Greater Chicago, IL. Dept. of Research and Development.
J. J. Bertucci, S. H. Abid, C. Lue-Hing, C. S. Clark, and J. D. Fenters.
Journal of Environmental Engineering, Vol. 109, No. 2, p 351-368, April, 1983. 1 Fig, 11 Tab, 18 Ref. EPA grants R803643, 805003.

Descriptors: *Viruses, *Wastewater, *Wastewater analysis, Raw wastewater, Effluent, Public health, Wastewater treatment.

Ninety-two treated and untreated sewage samples from seven wastewater treatment plants in Chicago, Illinois, Memphis, Tennessee, and Cincinnati, Ohio were examined for their virus content. Concentrated and unconcentrated samples were plaque assayed in five different cell culture systems. The virus etiology of plaques was confirmed by passage in homologous cell fluid cultures. Including all plaques tested, only 16.5 % were confirmed as of viral origin. BGM cultures produced the greatest number of unconfirmable plaques. Confirmed virus concentrations for individual samples ranged from less than 0.2 to 80 plaque forming units (PFU)/l. Confirmed PFU's/l averaged 0.7 for raw sewage, 0.5 for preliminary effluents and were not detected in final effluents. A strong recommendation of this study is that the virus etiology of all environmentally derived plaques must be confirmed. (Author's abstract)

INTERMITTENT SHALLOW AERATION OF ANAEROBIC LAGOONS TREATING PIGGERY WASTES,
Animal Research Inst., Victoria (Australia).
M. J. Ginnivan, and P. J. Eason.
Effluent and Water Treatment Journal, Vol. 23, No. 3, p 101 and 103-104, March, 1983. 4 Tab, 8 Ref.

Descriptors: *Animal wastes, *Wastewater treatment, *Aeration, Odor control, Lagoons, Bacteria, Fecal coliforms, Hydrogen sulfide, Anaerobic lagoons, Aerated lagoons, Streptococci.

The effect of intermittent aeration on the degree of odor control and the level of organic pollutants and bacteria in effluents from aerated-anaerobic lagoons was investigated. Perspex columns were used to simulate anaerobic lagoon profiles and were either unaerated (A), aerated for 15 min. and unaerated for 15 min. (B), aerated continuously (C) or aerated for 120 min. and unaerated for 120 min. (D). The average hydraulic retention time was about 128 days. All columns were initially seeded with sludge from an established lagoon which had been treating piggery wastes for 5 years. The mean temperature in all treatments was about 21.0 C and the average pH values were 7.8, 8.2, 8.4, and 7.05 for treatments A, B, C, and D, respectively. All treatments effectively removed organic pollutants from the waste. BOD5 and volatile solids reductions were at least 87 and 83%, respectively. The continuously aerated treatment was the most efficient. The average dissolved oxygen levels in treatments B, C, and D were about 67, 92, and 63% of saturation. While percentage reductions of fecal coliforms and fecal streptococci were high, there were still considerable numbers of viable bacteria in the effluent. The H2S levels associated with the unaerated treatment were above the level reported to present odor problems. H2S levels associated with the aerated treatments were lower than the detection limit of 0.1 ppm due to the ability of the sulfide to be rapidly oxidized. The individual volatile fatty acid concentrations in all treated effluents were less than 0.01 g/l, with the exception of acetic acid in treatment A which was about 0.1 g/l. While waste treatment was effective in all systems considered, the continuously aerated system consistently gave slightly better results than other methods. (Baker-IVI)

periments were conducted to compare the ter treatment efficiencies of plant-free mi- ters with filters supporting the growth of ragmites communis), cattail (Typha lati- h (Juncus effusus), and bamboo (Bambusa). The experimental systems consisted of ponents in series. The first component was obic settling-digestion container. The as a 'nonaerated' trough filled with rocks, decreasing from large rocks (up to 7.5-cm diameter) at the bottom, to pea gravel (0.25-to 1.3-cm diameter) at the top. The plant-free microbial filter was equally effective in carbonaceous BOD5 (5-d biochemical O2 demand) removal. The vascular aquatic plant series enhanced ammonia removal, and consequently improved nitrogenous BOD5 removal. Under the conditions of these experiments, raw sewage with initial BOD5's of 100 mg/L can be upgraded to meet secondary standards with 6 h in component 1, and 6 h in a plant-free filter or filter using cattail, rush, or reed. When initial BOD5's are approximately 450 mg/L, 24 h in component 1, 29 h in a reed filter are required to meet secondary standards. Total N removal studies were conducted, which demonstrated that a reed system is capable of removing NO3-N and NH3-N simultaneously, probably through a common NO2-N intermediary, then to N2. Overall, the reed system was superior to all others evaluated in this research project. (Author's abstract)

Journal of Environmental Health, Vol. 45, No. 6, p 276-282, May/June, 1983. 4 Tab, 63 Ref.

Descriptors: *Wastewater treatment, *Pollutants, *Chlorination, Carcinogens, Mutagens, Teratogens, Coagulation, Filtration, Sedimentation, Adsorption, Ozonation, Water treatment, Priority pollutants.

Recently, the list of 65 consent degree priority pollutants has been expanded to 129 more specific priority pollutants that have been assigned top priority for elimination from U.S. waterways. These pollutants are primarily carcinogens, mutagens, teratogens, and suspected carcinogens, and as such are of concern to environmental health professionals. To determine treatment process alternatives to conventional secondary treatment, which have the most significant effects on concentrations of the consent decree priority pollutants in water and wastewater, an extensive review of the literature was conducted. Five treatment processes which affected the greatest number and concentration of these pollutants were selected for summarizing. These processes are: lime coagulation, sedimentation, and sand or mixed media filtration; activated carbon adsorption; the EPA/Coast Guard Process for Toxic Spills; ozonation; and chlorination. It was determined that four of the five treatment processes could significantly reduce the concentrations of consent decree pollutants. However, chlorination, often legally required by state and public health agencies for surface drinking waters and for wastewaters, caused an increase in both the number and concentration of one-third of the priority pollutants. Pollutants not initially present in the water were produced from organic precursors, and pollutants already present were increased in concentration. (Moore-IVI)

MERCURY, A HAZARDOUS WASTE PROBLEM,
California State Univ., Fresno.
J. Weber.
Journal of Environmental Health, Vol. 45, No. 6, p 284-287, May/June, 1983. 16 Ref.

Descriptors: *Mercury, *Wastewater treatment, *Waste disposal, Heavy metals, Industrial wastes, Water pollution control, Land disposal.

Mercury, in all its chemical forms, is a known toxic substance. Historically mercury has been used in many areas such as art, medicine, industry and scientific research. Although the social benefits have been many, the environment has suffered from an increase in mercury levels due to careless disposal methods with resultant damage to humans and wildlife. Industrial contamination of the nation's waterways has necessitated the development of methods for removing mercury from industrial wastestreams. These methods include precipitation, ion exchange, adsorption on charcoal, solvent extraction and absorption with sulfides. The use of these procedures has reduced the amount of mercury going into the waterways significantly. Disposing of mercury in landfill sites can also be controlled using methods which will keep the mercury contained within solid leak-proof jackets of impervious clay formations. Handled with care, mercury is not a threat to humans or the environment. (Author's abstract)

THE EFFECT OF SUSPENDED SOLIDS IN WASTEWATER ON SOIL HYDRAULIC CONDUCTIVITY: I. SUSPENDED SOLIDS LABELLING METHOD,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Inst. of Soil and Water.
A. J. A. Vinten, U. Mingelgrin, and B. Yaron.
Soil Science Society of America Journal, Vol. 47, No. 3, p 402-407, May-June, 1983. 5 Fig, 4 Tab, 12 Ref.

Descriptors: *Suspended solids, *Land disposal, Wastewater disposal, Effluent, Radioactive tracers, DDT, Leaching, Soil physical properties, Mathematical models.

A method of labelling suspended solids in sewage effluent with C14-DDT (1,1,1, trichloro-2,2-bis(p-chlorophenyl)ethane) is presented. The method allows the vertical distribution of deposited solids in a soil, following leaching with effluent, to be determined. A simple physical model which describes transport of labelled suspension through the soil is developed. This enables the conditions necessary for successful utilization of the method to be defined. Procedures for the estimation of the parameters required for the model are presented and the application of the method is demonstrated for two soils. It is shown that the method for tracing the fate of suspended solids is valid, as long as the label is sufficiently strongly adsorbed on suspended solids. It is also required that the rate of desorption of label from suspended solids be low compared with the residence of mobile suspended solids in the soil. (Author's abstract)

THE EFFECT OF SUSPENDED SOLIDS IN WASTEWATER ON SOIL HYDRAULIC CONDUCTIVITY: II. VERTICAL DISTRIBUTION OF SUSPENDED SOLIDS,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Inst. of Soil and Water.
A. J. A. Vinten, U. Mingelgrin, and B. Yaron.
Soil Science Society of America Journal, Vol. 47, No. 3, p 408-412, May-June, 1983. 6 Fig, 13 Ref.

Descriptors: *Suspended solids, *Wastewater disposal, *Wastewater irrigation, Effluent, Permeability coefficient, Land disposal, Soil surfaces, Leaching.

A method for labelling of suspended solids in sewage effluent is used to trace the distribution of deposited solids in three soils following leaching with effluent. This distribution is related to the effect of sewage effluent application on the soil hydraulic conductivity. A sand, a sandy loam, and a loessial silt loam were studied. The reduction in relative hydraulic conductivity was greatest for the silt loam. This was due to accumulation of solids at the soil surface. In the sand little deposition of solids in the soil and little change in hydraulic conductivity occurred. Results indicate that with proper management sewage effluent can be used for irrigation without causing problems due to lack of soil permeability. (Author's abstract)

EFFECT OF TEMPERATURE ON THE GROWTH OF MICROBIAL FILM IN A MODEL TRICKLING FILTER,
Ashikaga Inst. of Tech. (Japan). Dept. of Civil Engineering.
Y. Honda, and J. Matsumoto.
Water Resources Research, Vol. 17, No. 4, p 375-382, April, 1983. 10 Fig, 2 Tab, 17 Ref.

Descriptors: *Trickling filters, *Temperature effects, *Biological Wastewater treatment, Biological oxygen demand, Growth kinetics, Autolysis.

The daily weight change of a microbial film in a model filter after the start of synthetic feed application was observed and the effect of temperature of the growth of the film was studied. The rate of BOD removal, the rate at which SS was washed out, the yield coefficient and the autolysis coefficient were chosen as the factors related to the growth of the film and the effects of temperature on them were examined. The growth pattern of the film can be divided into the lag-phase, growth-phase and stationary-phase. The growth equation of the film in the growth-phase was obtained by assuming that the rates of BOD removal and SS washed out were constant. In order to evaluate the growth of the film at various temperatures, the growth capacity and the mean growth rate were defined. The growth capacity is the film weight at the stationary-phase and expresses the maximum weight to which the film can increase in a given filter. The growth capacity increased as the temperature fell. This is due to the autolysis coefficient which becomes lower at low temperatures. The period necessary to reach the stationary phase was shorter at high temperatures. The mean growth rate, which was defined as the rate when the film has reached half the growth capacity, was at its maximum at 15 C. (Author's abstract)

OIL REMOVAL FROM WATER IN PARALLEL PLATE GRAVITY-TYPE SEPARATORS,
Amsterdam Univ. (Netherlands). Lab. of Chemical Technology.
J. A. Zeevalkink, and J. J. Brunsmann.
Water Research, Vol. 17, No. 4, p 365-373, April, 1983. 9 Fig, 4 Tab, 15 Ref.

Descriptors: *Separation techniques, *Oil pollution, *Gravity flow, Wastewater treatment.

Aspects of oil removal by gravity separation in parallel plate separators have been investigated both theoretically and experimentally. Attention has been paid to the possible influence of retention time distribution, co- or countercurrent flow (in tilted plate separators) and to the effect of perforation of the plates. Perforation enables an easy removal of separated oil in horizontal plate separators. It appears that the overflow rate, related to the horizontal projection of the real plate area, determines the performance of a plate separator in all these cases. A residence time distribution will lower the separation efficiency only when it is caused by a velocity profile over the width of the tank or by an extremely unequal distribution of the influent over the plates. A tilted full plate separator and a horizontal perforated plate separator with the same overflow rate perform equally well as to separation efficiency; only secondary, practical reasons will determine the choice between either construction. TESTING THE POTENTIAL OF AQUATIC PLANTS TO TREAT ABATTOIR EFFLUENT,
Commonwealth Scientific and Industrial Research Organization, Griffith (Australia). Div. of Irrigation Research.
C.M. Finlayson, and A. J. Chick.
Water Research, Vol. 17, No. 4, p 415-422, April, 1983. 3 Fig, 4 Tab, 32 Ref.

Descriptors: *Biological wastewater treatment, *Food-processing wastes, *Rooted aquatic plants, Cattails, Bulrushes, Phragmites, Trenches, Nutrient removal, Evapotranspiration, Oxygenation.

The potential of 3 genera of emergent aquatic plant species (Typha spp, Phragmites and Scirpus) to ameliorate effluent from a poultry abattoir was evaluated in an experimental trench system. Three plastic-lined trenches containing Typha (two species), Phragmites and Scirpus plants in a gravel substrate were constructed near the abattoir. Effluent was allowed to percolate, with retention times of 2.7 - 3.6 days, through the trenches. The quality of the inflowing and outflowing effluent was compared by a regular sampling program for suspended solids, conductivity, turbidity, pH, dissolved oxygen, Na, K, Cl, N and P concentrations. The importance of water loss by evapotranspiration was investigated. Comparing the inflow to outflow, each trench system successfully reduced the suspended solids (83-89%), turbidity (58-67%), total nitrogen (14-56%) and total phosphorus (37-61%) concentration of the effluent while maintaining an acceptable pH and in the case of the Phragmites and Scirpus systems oxygenating the anaerobic inflow. Conductivity increased in the Typha and Phragmites trenches. If a correction is made for water lost by evapotranspiration, the three experimental trench systems reduced the nitrogen (42-75%), phosphorus (68-79%), sodium (7-34%), potassium (9-56%) content of the effuent. The chloride content of the effluent in the Phragmites system was increased by 15% but was reduced by 31 and 53% in the Typha and Scirpus systems respectively. The results from this initial experiment give an indication of the relative abilities of the three plant systems to treat the wastewater from the abattoir. Of the three that containing the Scirpus was superior. (Author's abstract)

LIMITATIONS OF HEAVY METAL REMOVAL FROM WASTE WATER BY MEANS OF ALGAE,
Tuebingen Univ. (Germany, F.R.). Inst. fuer Chemische Pflanzenphysiologie.
E. W. Becker.
Water Research, Vol. 17, No. 4, p 459-466, April, 1983. 5 Fig, 4 Tab, 2 Ref.

Descriptors: *Heavy metals, *Biological wastewater treatment, *Phytoplankton, *Bioaccumulation, Biomass, Algae, Cyanophyta, Mercury, Cadmium.

It has been suggested by several authors that heavy metals might be removed from aqueous systems by phytoplanktonic algae, whose high capacity for accumulating dissolved metals has previously been described. This paper shows, by comparing results obtained on accumulation factors and growth rates in different modes, that metal removal by means of algae is not feasible in practice. It was found that under optimum conditions in a static system the reduction of a given initial metal concentration by 50% requires approximately 14 days, while in a dynamic model a retention time of approximately 19 days is needed to achieve the same reduction. Finally, measurements of nitrogenase activity inhibition caused by various concentrations of mercury and cadmium demonstrate that nitrogen-fixing blue-green algae can be used for biological sewage treatment only at very low heavy metal concentrations in the medium. MORE TO LEARN ABOUT DISINFECTION,
E. H. Bryan.
Water Engineering and Management, Vol. 130, No. 5, p 26-28, May, 1983. 2 Fig, 8 Ref.

Descriptors: *Sludge conditioning, *Disinfection, Wastewater treatment, Heat treatment, Electron beam, Bacteria, Pasteurization, Irradiation, Chlorination.

An inportant objective of wastewater treatment and sludge management is to reduce the content of pathogenic organisms to levels at which the risk associated with final release to the environment is reasonable and acceptable. The latest developments in the disinfection process for use by the wastewater industry are reviewed. Most of the known physical, chemical and biological agents that are capable of inactivating pathogenic organisms in water or wastewater are of little or no value for disinfection of sludges. Processes that have been shown effective for disinfecti sludges include heat pasteurization, treatmen excess lime, and irradiation with gamma ra energized electrons. An experimental full-scal using cobalt-60 as the source of gamma rad has been in operation for more than 7 yr in Germany. Research on the use of energized trons for sludge disinfection is underway. The ibility of using sludges in the production of led to a full scale test. The high temperatur several days of residence time within the kiln plant resulted in combustion of all organic m present in the sludge and the formation of a s product with the ash residue fixed within a ce matrix. During the past decade, the use of chl for disinfection of water and wastewater has subjected to increasing concern about pot risks associated with by-products of its use. (B IVI)

THE TRICKLING FILTER FINDS A N PARTNER,
Brown and Caldwell, Walnut Creek, CA.
R. C. Fedotoff.
Water Engineering and Management, Vol. No. 6, p 28-31 and 52, June, 1983. 1 Fig, 3

Descriptors: *Trickling filters, *Design crit Wastewater treatment, Filters, Filtration, C fiers.

After extensive evaluation, the trickling fi solids contact wastewater treatment process demonstrated great potential for future use. process developed out of experimentation cond ed at the Corvallis Wastewater Reclamation P where it involves primary sedimentation, two c ventional rock-media trickling filters, and an ated channel that carries wastewater to two cially designed secondary clarifiers with cen well flocculation chambers. Gentle stirring in t chambers increases the aggregation of finely di ed solids into heavy flow. This floc settles quic to the bottom of the clarifiers and is removed sludge. Part of the sludge is returned to the aer contact channel, mixed with the trickling fi effluent and recirculated to the clarifiers. The mainder of the sludge is pumped to the prim sedimentation tank as waste. The process functi effectively wherever the trickling filter proces applicable, largely because of the flexibility m possible by tradeoffs in the design of its com nents. An initial design consideration is the size the trickling filter which governs the quality of wastewater entering the aeration system. Variat that give the process additional flexibility are size and residence times in the aerated contact a the return sludge aeration tanks. (Baker-IVI)

Water Services, Vol. 87, No. 1046, p 163-1 April, 1983. 2 Fig, 4 Tab.

Descriptors: *Ozonation, *Odor contro *Wastewater treatment, Ozone, Wet oxidati process, Disinfection, Water treatment odors.

The nature of the solution to odor problems e countered in the treatment of sewage may often found in a deeper understanding of the compl nature of the problem. Such matters as the dilutio factor and odor emission values must be measur and determined. The capital cost of any od abatement system is to a large extent dependant o the air flow involved. Extraction rates should b kept to the minimum sufficient to not only preve leakage of odors but also to prevent potential dangerous conditions from occurring As an exam ple of a method of abatement the wet oxidatio process is considered. The use of ozone durin sewage treatment reduces both the amines an sulfur compounds and further reduces them afte scrubbing. In addition to the odor problem, there also the problem of pollution by microbiologica contamination of the environment around a sewag

ent works. The ozone wet oxidation process able to remove a large proportion of the iological contamination collected through tion systems in enclosed plants. (Baker-IVI)

THEORY OF CLARIFIER OPERATION. VI. THE PRECIPITATION PROCESS IN REACTOR-CLARIFIERS,
Vanderbilt Univ., Nashville, TN. Dept. of Chemical Engineering.
R. M. Strang, K. B. Schnelle, Jr., and D. J. Wilson.
Separation Science and Technology, Vol. 18, No. 3, p 253-291, 1983. 23 Fig, 5 Tab, 19 Ref.

Descriptors: *Clarifiers, *Wastewater treatment, Metal-finishing wastes, Settling velocity, Chemical treatment, Flocculation, Mixing, Ferric hydroxide, Mathematical models.

Reactor-clarifiers are widely used for removal of metals from metal finishing wastewaters. They are similar to standard upflow clarifiers except that the addition of chemicals and the precipitation of solids takes place within the clarifier. A mathematical model is developed for the effect of the rapid-mix step on floc settling velocity in reactor clarifier operation. Data on ferric hydroxide flocs are consistent with the model. The most important parameter is the duration of the rapid-mix step; the longer this is, the more slowly does the floc settle. This is thought to be due to the finite rate at which the precipitation reaction causes the supersaturated solution to decay to equilibrium. There is a possibility of improving the performance of upflow clarifiers by bypassing a small fraction of the influent around the precipitator and introducing it, with mixing, at the entrance to the clarifier. Preliminary pilot scale studies on this look promising. (Moore-IVI)

SIGNIFICANCE OF ATP IN THE SETTLEMENT OF ACTIVATED SLUDGE,
Birmingham Univ. (England). Dept. of Civil Engineering.
A. R. Clarke, and C. F. Forster.
Journal of Chemical Technology and Biotechnology, Vol. 33B, No. 2, p 127-135, June, 1983. 7 Fig, 27 Ref.

Descriptors: *Sludge drying, *Adenosine triphosphate, Activated sludge process, Sludge volume index, Wastewater treatment, Settleable solids, Model studies, Sludge.

The settleability of sludge in relation to its adenosine triphosphate (ATP) concentration was examined using a laboratory-scale activated sludge plant for the treatment of simulated coke oven liquors. Throughout the test the average flow rate was maintained at 2.23 liters/day and the mixed liquor solids at 3.9 grams/liter. The feed-stock contained phenol and thiocyanate as the carbonaceous substrate. Standard analytical procedures were employed. A model describing sludge settlement was derived, based on the concept that the Mohlman or Sludge Volume Index (SVI) is the summation of the individual component settlement indices and that these are dependent on the individual microbial activities as measured in terms of the ATP concentration. Data to validate the model were obtained from a continuous 40 day period of operation during which time the sludge exhibited a series of settlement characteristics with SVI values ranging from 65 to 270. At very high SVI values it was necessary to add small quantities of silicone anti-foam to prevent the sludge buoying in the settlement tank and thereby creating problems of inadequate solids recycling and sludge losses. A linear correlation was supported between the SVI and the mass of ATP per unit mass of sludge solids. Thus, variations in the settlement characteristics of activated sludge, measured in terms of the SVI, can be explained in terms of ATP-activity of the sludge solids and conventional Monod kinetics. CHARACTERISTICS OF COMBINED EFFLUENT TREATMENT SLUDGES FROM SEVERAL TYPES OF PULP AND PAPER MILLS,
Wisconsin Univ.-Madison.
J. N. McGovern, J. G. Berbee, J. G. Bockheim, and A. J. Baker.
Tappi Journal, Vol. 66, No. 3, p 115-118, March, 1983. 1 Fig, 5 Tab, 11 Ref.

Descriptors: *Sludge disposal, *Pulp wastes, Pulp and paper industry, Industrial wastes, Effluent, Sludge composition, Wastewater treatment, Heavy metals, Nutrients, Wisconsin River.

Combined sludges from 7 primary-secondary effluent treatment systems serving 10 highly diversified pulp and paper operations on the Upper Wisconsin River were analyzed for total solids, carbohydrates, ash, and elemental composition, including plant nutrients and heavy metals. The 7 treatment plants serve 7 integrated wood pulp mills, an integrated recycling mill, a nonintegrated paper mill with a recycling paperboard operation, and a kraft-wood pulp mill. The total daily production of combined sludges from the 7 treatment plants in early 1980 was 199 metric tons. The characteristics of the 7 sludges varied several- fold with pulping and papermaking processes and operations and effluent treatment. Balances were developed between wood and process chemical elements and those elements of the sludges. The suitability of the sludges for land spreading and incineration is considered. (Moore-IVI)
W84-01186

SORPTION AND RELEASE OF CADMIUM BY SOME SEWAGE SLUDGES,
R. Riffaldi, R. Levi-Minzi, A. Saviozzi, and M. Tropea.
Journal of Environmental Quality, Vol. 12, No. 2, p 253-256, April-June, 1983. 1 Fig, 6 Tab, 24 Ref.

Descriptors: *Cadmium, *Sludge, *Adsorption, Fulvic acids, Cation exchange, Langmuir equation, Bonding.

Sorption and release of Cd were determined in nine sewage sludges from Tuscany, Italy. The Cd adsorption data were in agreement with both the linear sorption isotherm and the Langmuir equation. The average of calculated adsorption maxima was about 50% of the mean CEC value, indicating that exchangeable cations present in the sludges were more effective in competing with the Cd ion for exchange sites. The calculated Langmuir adsorption maxima were found significantly correlated with fulvic acid C content and carboxyl and phenolic hydroxyl groups of fulvic acids. The release of Cd retained at two initial concentrations as a function of different extraction solutions was indicated. Extraction experiments showed that Cd may be held in sludges by more than one type of site and that the strength of bonding decreases as the total Cd increases. Cadmium was retained mainly by exchange and complexing sites, the former assuming a relatively more important role as cadmium adsorption increased. The effect of

different exchangeable cations on the sorption of Cd by sludges was also studied. The amounts of Cd sorbed on the sludge surfaces decreased in the order: Ca-sludge > untreated sludge > Fe-sludge = Al-sludge. (Author's abstract)

BEHAVIOR OF CHROMIUM IN SOILS: V. FATE OF ORGANICALLY COMPLEXED CR(III) ADDED TO SOIL,
Cornell Univ. Agricultural Experiment Station, Ithaca, NY. Dept. of Agronomy.
B. R. James, and R. J. Bartlett.
Journal of Environmental Quality, Vol. 12, No. 2, p 169-172, April-June, 1983. 6 Fig, 9 Ref.

Descriptors: *Chromium, *Solubility, *Land disposal, *Sludge disposal, *Wastewater disposal, Organic acids, Heavy metals, Soil contamination.

Organically complexed Cr(III) added to soils may remain soluble, whereas the free Cr(III) metal ion would quickly become adsorbed and/or hydrolyzed and precipitated in the absence of soluble, complexing ligands. To separate these two phenomena, a laboratory procedure was developed to simulate the disposal of Cr(III)-containing organic wastes in soils, and to investigate the solubilities of organic complexes of this heavy metal after addition to soil. The method involves adding Cr(N3)3 to solutions of organic ligands adjusted to a pH between 3 and 8 to form inorganic hydrolyzed species and organic complexes at each pH. After measuring soluble Cr vs. pH, moist soil is added to bring the pH of each Cr-ligand system to 6.5-7.0, thereby precipitating uncomplexed, inorganic Cr(III), and labile Cr(III)-organic complexes. Subtracting Cr(VI) formed from total soluble Cr in the soil suspension gives a relative measure of organically complexed Cr(III) originally present in the aqueous systems at each pH. Citric acid, diethylenetriaminepentaacetic acid (DTPA), fulvic acids, and water-soluble organic matter from air-dried soil kept Cr(III) in solution above pH 5.5, and prevented its immediate removal by soil. Added Cr-citrate remained soluble for at least 1 y in limed samples of an Ultic Hapludalf Ap horizon incubated at field capacity moisture. Because organic acids similar to those studied here may be found in sewage sludge, animal manures, and industrial wastewater, these results should be useful in predicting the fate of Cr(III) added to soils amended with such wastes. (Author's abstract)

SLUDGE DISINFECTED WITH ELECTRON BEAMS,
Ion Physics Corp., Burlington, MA.
J. Morgan.
Water Engineering and Management, Vol. 130, No. 5, p 27-28, May, 1983.

Descriptors: *Sludge conditioning, *Electron beams, *Disinfection, Sludge disposal, Liquid sludge.

Electron beam disinfection was shown to be not only feasible, but also cost-effective for treating municipal sludge. Liquid sludge flows in a vertical free fall as a thin curtain a little over 4 ft wide. As it falls, the sheet of sludge is exposed to a beam of electrons energized by 1.5 million volts with a power of 75 kw. Disinfection takes place in the fiftieth of a second that it takes the sludge to fall through the scanning electron beam. Dosage levels are about 400 krads which raises the temperature of the water only 1 degree C, but reduces the total bacterial count by four or five orders of magnitude. After electron exposure is completed, the effluent line is sampled by a system. The sample plunger extends forward into the process line and pauses. It then withdraws a precise sample regardless of changes in line pressure or other parameters. This final checkpoint assures that the pathogen level of outgoing effluent is below the EPA limit. It also permits analyses of the sludge for water soluble compounds of such metals as cadmium, chromium, copper and lead. At current rates the disinfection of 1,000 gal of liquid sludge, treated with a 400 krad electron dosage requires about 20 kwh of power and costs about $4.00. For sludge containing 4% solids, this is equivalent to about $24.00 per ton of dry material. (Baker-IVI)

5F. Water Treatment and Quality Alteration

CONCENTRATION OF SIMIAN ROTAVIRUS SA-11 FROM TAP WATER BY MEMBRANE FILTRATION AND ORGANIC FLOCCULATION,
Hadassah Medical School, Jerusalem (Israel). Environmental Health Lab.
N. Guttman-Bass, and R. Armon.
Applied and Environmental Microbiology, Vol. 45, No. 3, p 850-855, March, 1983. 1 Fig, 7 Tab, 19 Ref. EPA grant R 806588010.

Descriptors: *Rotaviruses, *Drinking water, *Membrane filters, *Flocculation, Viruses, Water analysis, Public health, Microporous filters, Water treatment.

Rotaviruses are viral agents of gastroenteritis in animals and humans. For determination of the extent of contamination of the environment with these viruses it is essential to have a reliable and sensitive technique for their detection. Most methods of virus concentration have been developed with poliovirus as a representative virus, but this virus differs from rotavirus in many characteristics, including adsorptive behavior and stability. Because simian rotavirus SA-11 resembles the human rotavirus, it is useful as a model for the human disease agents. Two types of filters were compared for their ability to concentrate this virus. Both Zeta Plus 60S and Cox AA type M-780 filters were efficient for virus adsorption, but the efficiency of virus elution was higher with Zeta Plus than with Cox filters. Optimum conditions for virus recovery from Zeta Plus filters included an input water pH of 6.5 to 7.5 and the use of 3% beef extract (pH 9.0) for elution. Under these conditions, an average of 62 to 100% of the virus was recovered in the concentrate. Organic flocculation was used as a second-step concentration method, with average recoveries of 47 to 69%. When the two methods were used to concentrate small numbers (7 to 75 plaque forming units/liter) of input rotavirus, an average of 75 + or - 40% recovery was achieved. With large volumes of input water, recovery was reduced to 16 + or - 7%. (Moore-IVI)

The town of Toutle, approximately 26 mi northwest of Mount St. Helens, has utilized a shallow, high capacity well completed in recent alluvium of the South Toutle River for its water supply since 1974. Debris and mudflow following the May 18, 1980 eruption buried the well and the nearby treatment facility. The town immediately went on water rationing, and tank trucks were employed to haul water to the Toutle Reservoir. Reconnaissance field work showed inadequate stream base flow and no reservoir sites as well as poor infiltration gallery sites along Outlet Creek. Two test wells were drilled on the South Toutle bridge abutment near the old well. Drawdown/recovery tests showed either well capable of producing the necessary sustained yield of 200 gpm. Toutle residents soon complained of an objectionable water taste and medicinal odor. Testing showed the presence of up to 80 micrograms/l total phenols. Phenolic compounds are derived from decaying vegetation, and slow dewatering of the mudflow and debris materials into the underlying alluvium accounted for the microconcentrations of p

WATER QUALITY FROM WATER-HARVESTING SYSTEMS,
Agricultural Research Service, Tucson, AZ. Southwest Watershed Research Center.
G. W. Frasier.
Journal of Environmental Quality, Vol. 12, No. 2, p 225-231, April-June, 1983. 2 Fig, 6 Tab, 12 Ref.

Descriptors: *Water harvesting, *Drinking water, *Water quality, Arizona, Heavy metals, Arsenic, Precipitation, Runoff, Dusts.

Water harvesting is a technique used to supply animal and domestic drinking water in areas where more conventional methods cannot supply sufficient water. The water collected by a water-harvesting system has the potential of being contaminated by deterioration by-products of the materials used in constructing the system, from dust that is deposited on the catchment surface, or from impurities trapped in the rain. During a 3-y period, runoff water samples were collected for water quality analyses from 10 types of catchment treatments on operational and experimental water-harvesting systems in Arizona. Atomic absorption spectrophotometry techniques were used to determine the concentrations of Al, As, Cd, Ca, Cr, Co, Cu, Fe, Pb, Mg, Hg, K, Na, V, and Zn in each water sample. There was no evidence that deterioration of the catchment treatments would cause a contamination of the runoff water. With the exception of As, most samples had significantly lower concentrations of these constituents than the maximum standards for animal or domestic drinking water supplies. Arsenic was the only chemical consistently found in the water samples at potentially hazardous concentrations for domestic drinking water supplies. Excessive As concentrations were not associated with any specific type of catchment treatment. The logarithm of As concentration in the runoff was positively correlated with the logarithm of the time since the previous rain, and negatively correlated with the logarithm of the total rainfall quantity. Apparently, As was deposited on the catchment surface as dryfall dust, and/or was washed from the atmosphere by the rainfall. (Author's abstract)

EVALUATION OF CARTRIDGE FILTERS FOR THE REMOVAL OF GIARDIA LAMBLIA CYST MODELS FROM DRINKING WATER SYSTEMS,
Sequoia and Kings Canyon National Parks, Three Rivers, CA.
W. R. Long.
Journal of Environmental Health, Vol. 45, No. 5, p 220-225, March/April, 1983. 7 Fig, 7 Tab, 6 Ref.

Descriptors: *Cartridge filters, *Drinking water, *Giardia cysts, Protozoa, Water treatment, Filtration, Particle size, Turbidity, Sand filters.

Numerous waterborne outbreaks of Giardiasis have occurred in recent years in many areas of the United States. Since Giardia lamblia cysts are resistant to chlorination, removing cysts by filtration would be a solution to water treatment. Cartridge filters were analyzed for filter efficiency by the use of turbidity measurements, particle size analysis and scanning electron microscopy analysis. The cartridge filters were challenged by a solution of microspheres (5.7 micrometers in diameter, which is smaller than a Giardia lamblia cyst) at a concentration of 40,000 to 65,000 spheres per ml. Calculations were then performed for turbidity reduction, particle number reduction and visual counts of microspheres. Ten of 17 cartridge filters removed over 99.99% of the microspheres. These would also be effective in removing Giardia lamblia cysts. In several cases, actual performance differed from the manufacturer's micrometer retention rating of the filter. Sand media were not effective in removing the microspheres. (Author's abstract)

ROUTINE COLIFORM MONITORING AND WATERBORNE DISEASE OUTBREAKS,
Columbia Univ., New York. School of Medicine.
O. Batik, G. F. Craun, and W. O. Pipes.
Journal of Environmental Health, Vol. 45, No. 5, p 227-230, March-April, 1983. 3 Tab, 6 Ref.

Descriptors: *Coliforms, *Drinking water, *Waterborne disease, Bacteria, Water quality standards, Water quality, Human diseases.

A comparison of coliform monitoring results was made between water systems experiencing a waterborne outbreak and systems in which an outbreak had not been reported. In a study of community systems, the outbreak and comparison communities were not found to differ in regard to positive coliform results within the three months prior to the outbreak. Also, no statistical difference was observed between outbreak and comparison communities with respect to the number of times the coliform standard was exceeded per number of samples collected and mean number of coliform organisms in the water system during an entire three year period. A study of coliform monitoring results for non-community systems in Pennsylvania show no difference in positive coliform results between non-community systems experiencing an outbreak and those not experiencing one. These data provide no evidence that coliform monitoring provides any prediction of outbreaks of waterborne disease in non-community systems. These results must be interpreted cautiously for several reasons, including small sample size and incomplete reporting of waterborne outbreaks. It is suggested that regulatory agencies should carefully examine the relative importance of the routine coliform monitoring of tap water in the surveillance of waterborne disease. (McKeon-IVI)

USE OF A PILOT PLANT TO IMPROVE WATER TREATMENT CONDITIONS,
W. B. Thomas.
Power Engineering, Vol. 87, No. 9, p 54-55, September, 1983. 1 Fig.

Descriptors: *Pilot plants, *Water treatment facilities, Cooling towers, Demineralization, Desalination.

Use of a small pilot plant, designed to duplicate as nearly as possible the conditions in the full scale equipment, can yield valuable operating data and suggest improvements in the design of the full sized facility. A pilot plant for a demineralization system should duplicate the full sized equipment except for instrumentation. Flow rates during demineralization, rinse, chemical injection and backwash should be the same, but flow distribution, bed pressure drop, and proper backwash bed expansion should not be duplicated. Once the pilot plant is operable the first exercise should be operator training as experience gained will enable operators to more quickly spot malfunctions. After the full sized facility is operating, pilot plants can still be used to study possible improvements in the system, to evaluate the use of new cleaners and other chemicals. With the growing emphasis on plant effluent reduction, pilot sized equipment is becoming increasingly useful in evaluating cooling system operation. The effect of higher water concentrations can be studied without the danger of increased fouling, heavy scaling, or corrosion. (Baker-IVI)

MANAGING A WATER UTILITY,
Richardson Dept. of Public Services, TX.
M. L. Haney.
Southwest and Texas Water Works Journal, Vol. 64, No. 12, p 4-6, 20 and 22, March, 1983.

Descriptors: *Public utilities, *Professional personnel, *Metropolitan water management, Texas, Water quality management.

The major duty and responsibility of any utility manager is to provide good, safe, and potable water to his customers in the quantity required. He must then safely remove the amount of water that

becomes waste and see that this waste does not become a health hazard. The major cost of operating a utility is personnel, and the training, management, and dedication of this personnel is most important. Professional obsolescence is a major hazard as more automation of services and computerization of requirements demands top efficiency from skilled workers. (Wheatley-IVI)

PRIVATIZATION OF WASTEWATER TREATMENT,
Young (Arthur) and Co., New York.
H. J. Goldman, and R. D. Vought.
Southwest and Texas Water Works Journal, Vol. 65, No. 3, p 5-6, June, 1983.

Descriptors: *Wastewater treatment, *Economic aspects, *Private ownership, Community development, Cost allocation.

The private sector has an excellent track record in building and operating wastewater treatment plants to serve its own needs. The economics of owning and/or operating treatment facilities are attractive to the private sector. Privatization is cost effective for the communities as well. It can even compare favorably to a federal grant in terms of user fees. There are several ways in which privatization can be implemented: development of industrial on-site treatment facilities with expansion potential for community growth requirements, sale of community treatment facilities to a local industry, or construction by a private group to service both community needs and industrial requirements. The need for state participation in fostering privatization is evident. Privatization of wastewater treatment is a viable alternative to the financing crisis facing many communities. Privatization is just at the starting line. The private sector is interested, the environmental regulatory agencies are supportive, and the public needs it. (Wheatley-IVI)

GOING DEEP CUTS SEWER, LIFT STATION COSTS,
Winzler and Kelly, Eureka, CA.
M. Kincaid.
Water Engineering and Management, Vol. 130, No. 4, p 26-27, April, 1983. 2 Fig.

Descriptors: *Wastewater facilities, *Pipelines, *Pumps, *Groundwater, Soil water table, California, Costs.

In addition to challenging geotechnical and hydrologic problems encountered during the construction of a pair of Crescent City, California wastewater collection systems, the contractors also had to deal with some touchy archaeological situations. An increase in the number of hepatitis cases in this urban area indicated the need for the updating of the wastewater treatment system. High groundwater was a common problem in the planned construction of the new pipelines. The cost for multiple lift stations required by an above groundwater pipeline system made the cost of a deeper system with fewer lift stations more cost effective. In the construction phase, several burial sites were encountered requiring rerouting of some of the pipelines. Early in 1981, the last segment of the project was completed and placed in operation. SOFTWARE SOLVES WATER SUPPLY PROBLEMS,
H. Rogers.
Water Engineering and Management, Vol. 130, No. 4, p 38-39, April, 1983.

Descriptors: *Computers, *Water supply systems, Management planning, Water supply, Water demand, Water distribution, Costa Rica.

Hydraulics and water resource studies are areas of rapid advancement in computer software technology. It is now possible to take a complete water supply system and analyze it as it stands without alteration or simplification. This new technology was used in a Costa Rica project called the San Jose Water Supply - Stage 2 of the Distribution System - Second Computer Model. The objective was the creation of a computer model in San Jose to serve as a design tool for Costa Rican engineers, enabling them to study the performance of the system and to design extensions as the city expands. The version of the software tailored for use on this computer can analyze a network containing up to 200 nodes and 250 connectors. This computer system has also been used in projects involving communities of populations ranging from 250,000 to 1,250,000. Other water related software programs include AQUIFER, which simulates groundwater levels in an aquifer under complex conditions, SLIPSERF, which is an interactive program for the rapid and economic location of the critical slip circles of non-homogeneous slopes under varying conditions, and LMGEN, which comprises three programs for sewer design. CLEAR WATER FOR CAYUGA,
MacNeill (John S.) Jr., Homer, NY.
A. W. MacNeill, and J. M. Scanlon.
Water Engineering and Management, Vol. 30, No. 5, p 41-42, May, 1983. 3 Fig.

Descriptors: *Turbidity, *Water treatment facilities, *Water quality control, Drinking water, Lakes, Lake Cayuga, New York, Filtration, Clarification, Clarifiers.

Cayuga Lake provides the potable water supply for an upper New York State village with a population of about 600 and an adjacent town with 92 residential connections. The existing water treatment plant, built in 1935, provides an average of 125,000 gpd of water. The system consists of an intake structure 300 ft offshore and a low pump head to transfer water through an aerator. Water flows from the aerator by gravity through a settling tank and on to a rapid sand filter. Once the filtered water is chlorinated it is discharged to a wet well below grade. Water is delivered through high pressure injection pumps at a rate of 150 gpm. Turbidity levels in the raw water of the lake vary from 1-100 NTU. The high turbidity breakthrough that occurs in the water system is largely due to storm water run-off and wave action in the lake. To combat this problem water is pumped through a cyclone separator. Downstream from the separator, alum is injected into the water at a rate of 10 mg/l to neutralize the electric charge of the suspended particles and form a precipitate. A depth clarifier acts as a contact flocculator. Effluent from the depth clarifiers is fed to a depth filter. A granular carbon system for polishing the water brings the quality within prescribed guidelines. The innovative design includes a top layer of petroleum base carbon with a fine garnet bed to prevent dusting or loss of minute carbon particles in the finished water. Post chlorination is the final step. (Baker-IVI)

res have been developed for designing material sedimentation basins. These pro- can also be used for designing sedimenta- ns for other slurries having high suspended ncentrations. Dredged material sedimenta- ns are slightly different from those used in nd wastewater treatment in that the material basins must provide for sedimen- achieve acceptable effluent quality while providing storage volume for several years of material dredged from local waterways. Guidance is presented for field sampling and laboratory testing required to obtain data for sediment characterization, data analysis, sedimentation basin (containment area) design, and estimating storage capacity required. Settling tests performed in a 8-in. (20 cm) diameter column were found to be satisfactory for defining dredged material settling behavior. Settling behavior in the freshwater environment was best described by a flocculent settling test, while behavior in a salt-water environment was best described by a zone settling test. Procedures are presented for designing new containment areas for suspended solids retention and for evaluating the suspended solids retention potential of existing containment areas during planned disposal activities. The field verification work performed during this research indicated that conservative values could be estimated from laboratory tests for solids concentrations expected in the dredged material sedimentation basins. FEATURES OF FEDERAL LAW THAT ENCOURAGE ADOPTION OF LAND APPLICATION OF WASTEWATER,
Wisconsin Univ.-Madison. Law School.
D. T. Massey.
Journal of Water Resources Planning and Management, Vol. 109, No. 2, p 121-133, April, 1983. 36 Ref.

Descriptors: *Land disposal, *Wastewater disposal, *Sludge disposal, *Legal aspects, Federal jurisdiction, Regulations, Public policy, Water pollution control, Effluents, Standards.

Federal statutes and regulations and Environmental Protection Agency (EPA) guidelines and policies tend to aid and encourage land application of municipal wastewater effluents and sludges and make the method of treatment increasingly attractive. Land application systems are made more attractive by federal law relating to eliminating the discharge of pollutants into navigable waters, stringent standards on discharges from treatment works, and restrictions imposed on permits for discharging effluents and sludges into navigable waters and the ocean. Provisions of federal law tending to aid and encourage land application systems relate to cost-share grants for construction of treatment works, level of effluent and sludge treatment prior to application on land, pretreatment requirements for pollutants introduced into treatment works, federal grants awarded for research and demonstration projects, and requirements for developing public information and education programs. MINNESOTA'S HAZARDOUS WASTE SITING CRITERIA,
Minnesota Waste Management Board, Crystal.
A. P. Shilepsky, and R. B. Pulford.
Journal of Water Resources Planning and Management, Vol. 109, No. 2, p 165-173, April, 1983. 1 Fig, 1 Tab, 7 Ref.

Descriptors: *Waste disposal, *Environmental protection, *Site selection, Legislation, *Minnesota, Management, Groundwater management, Hazardous materials.

Minnesota currently has no commercial hazardous waste disposal facility. Therefore the 1980 Minnesota Legislature created the Waste Management Board, responsible for siting at least one land disposal facility and having the authority to condemn land and supersede local zoning. Minnesota rules prohibit facility location within 1,000 ft of a protected lake, pond, or flowage, or within 300 ft of a protected stream. Siting is also prohibited in natural marshes 10 acres and larger which are eligible for classification as US deep, or open fresh water marshes. Due to the hydrogeologic unpredictability in a topography characterized by sinkholes, caves and underground drainage, attempts were made to remove karst development areas from consideration. Analyses must be performed to determine if leachate, run-off, or other natural processes occurring during facility development will affect nearby protected waters or wetlands. Since both rivers and lakes may be surface sources of drinking water in the state, concern was expressed by some citizens that any downstream water intake, regardless of distance, should eliminate a site from further consideration. The Waste Management Board did not share this view. In order to protect groundwater from contamination, consideration was given to sites which were clay-rich quarternary deposits where regional data indicated sustained well yields of one gallon per minute or less; devoid of major buried quarternary aquifers; composed of Precambrian igneous and metamorphic bedrocks as these are nonaquifers; and possessing a 50 ft or more depth to bedrock. When the site selection was narrowed down to only 20 possibilities, a drilling program was used to further define the groundwater situation, with the presence of an aquiclude becoming a requirement. Specific monitoring methods are to be part of the engineering design examined in the Environmental Impact Statement. (Baker-IVI)

GROUND-WATER MOUNDING DUE TO ON-SITE SEWAGE DISPOSAL,
Santa Clara Univ., CA. Dept. of Civil Engineering.
E. J. Finnemore, and N. N. Hantzche.
Journal of Irrigation and Drainage Engineering, Vol. 109, No. 2, p 199-210, June, 1983. 7 Fig, 1 Tab, 16 Ref. EPA grant P009211010.

Descriptors: *Groundwater mounding, *Wastewater disposal, *Soil disposal fields, Mathematical studies, Wastewater management, Sites, Geohydrology.

Localized ground-water mounding beneath larger on-site sewage disposal fields (leach fields) may be a major problem which previously had not been adequately addressed. Existing methods to predict mounding, mainly developed for ground- water recharge spreading basins, are reviewed for applicability to sewage disposal fields. A most appropriate and accurate method is selected and considerably simplified to provide a convenient, straightforward prediction procedure for regulatory agencies and designers. The major simplification, to a single equation, is particularly accurate after longer wastewater application times, of say 10 to 20 years, when mounding is of most concern. Sensitivities of the procedure to the various simplifications, site factors, and design and management options are discussed and presented in graphical form where significant. Alternative means to reduce mounding are reviewed. Mounding problems and potential mitigation measures should be made more widely known, and long-term field verification of the theory is needed. HOW MASSACHUSETTS PLANS TO MEET THE WATER SUPPLY CHALLENGE OF THE 1980'S,
Massachusetts Div. of Water Supply, Boston.
I. Bhatti.
Journal of the New England Water Works Association, Vol. 97, No. 2, p 114-118, June, 1983. 4 Ref.

Descriptors: *Water supply development, *Water quality control, *Massachusetts, Resources management, Water management, Water shortage, Groundwater management, Water conservation.

New demands for purity and adequacy of supply are being placed on water managers who operate water supply systems and on water regulatory agencies which are responsible for regulating the quality and quantity of drinking water. More than 95% of the population of Massachusetts is served by some form of public water system and the remaining population gets drinking water from individual on-lot wells. More than half the communities are dependent on groundwater sources. A total of 758 municipal water supply wells were recently tested for quality control, with one-third showing detectable amounts of volatile organics and three exceeding the acceptable levels. Water quantity problems also exist in the state, with a rash of

communities experiencing water shortages in 1980 and 1981. Statewide demand has increased from 91 GPCD in 1950 to about 150 GPCD in 1980 and will, at this rate, reach a deficit of 70-140 MGD for eastern Massachusetts by 1990. In an attempt to improve this situation, Chapter 286 of the Acts of 1982 was passed in July of 1982 providing $107.5 million for water supply purposes with $60 million set aside for a Leak Detection and Rehabilitation Program, $25 million for construction of water filtration plants, $10 million for water supply contamination clean-up and to provide a temporary water supply, $2.5 million for water conservation devices in public buildings; and $10 million for the acquisition of land to protect future groundwater sources. WATER UTILITY COMPLIANCE WITH HAZARDOUS MATERIALS, SUBSTANCES AND WASTE REGULATIONS,
Connecticut Water Co., Clinton.
T. R. Marston.
Journal of New England Water Works Association, Vol. 97, No. 2, p 134-137, June, 1983.

Descriptors: *Regulations, *Hazardous materials, *Utilities, Sludge, Water treatment facilities, Wastewater.

One area of concern is the transporting of treatment chemicals from a central location to outlying treatment stations by water department trucks. The most difficult aspect of complying with the regulations for transporting hazardous materials often concerns shipping papers. If an amount of a hazardous substance equal to or greater than its reportable quantity is to be transported, it must be so noted on the shipping papers. Concerning waste generated by the water industry, the largest quantity is sludge which is not classified as a hazardous waste by the EPA. However, there is concern over the possible toxicity of this material. Additional hazardous wastes can be generated at water utilities if a company cleans water meters in an acid or caustic solution or if spills in the chemical feed system are retained in a vault or waste tank. If a company generates less than 1000 kg (454 lb) of waste in a calendar month, it is classified as a small quantity generator and does not have to meet the registration, personnel training, contingency planning and emergency requirements of a larger generator of hazardous waste. A small quantity generator must still handle and dispose of the waste in such a way as to meet all regulatory requirements, including packaging, marking and labeling waste to meet all Department of Transportation regulations as well as additional EPA marking requirements for hazardous waste, and offering the waste to a licensed transporter for disposal at a licensed treatment, storage and disposal facility. MANAGING RUNOFF FROM A SMALL, PAVED BEEF FEEDLOT,
Science and Education Administration, Coshocton, OH. North Appalachian Experimental Watershed.
W. M. Edwards, L. B. Owens, and R. K. White.
Journal of Environmental Quality, Vol. 12, No. 2, p 281-286, April-June, 1983. 8 Fig, 2 Tab, 14 Ref.

Descriptors: *Feedlot runoff, *Water pollution control, Wastewater management, Storm runoff, Settling basins, Filter strips, Nutrients, Biological oxygen demand, Chemical oxygen demand, Settleable solids, Infiltration.

Each year for 3 yr, 56 steer calves were fed to market weight on a corn-silage and shelled-corn ration in a 243-sq m paved lot. Storm runoff was measured and sampled as it left the feedlot, and again after it passed through a shallow, concrete settling basin and two consecutive 30 m long by 4.5 m wide sod filter strips. Storm runoff amounts and transport of TS (total solids), COD (chemical oxygen demand), BOD5 (5-d biological oxygen demand), N (total nitrogen), and P (total phosphorus) were smaller during the fall and winter months, when the steers were small and being fed silage than during May through July, when the animals were larger and eating shelled corn. The settling basin reduced transport of TS and COD by about 55%, while retaining only 35-40% of the BOD5, N, and P. Total reduction of all parameters was increased to 80-90% in the filter strips. The basin was more effective in large storm events, and the filter strips were more effective when the basin was slowly drained after settling of the settleable solids. Rainfall on the filter strips reduced the concentration of all parameters during large storms, and infiltration during other events reduced transport to downstream areas. (Author's abstract)

EFFECTS OF POPULATION AND INDUSTRIAL CHANGE ON ENVIRONMENTAL QUALITY IN MAJOR CONURBATIONS,
Victoria Univ. of Manchester (England). Dept. of Economics.
N. Lee, and C. Wood.
Journal of Environmental Management, Vol. 16, No. 2, p 91-107, March, 1983. 3 Fig, 5 Tab, 30 Ref.

Descriptors: *Urban areas, *Environmental quality, Industrial wastes, Domestic wastes, Human populations, Population dynamics, Urban planning, Forecasting, Environmental control.

The environmental quality which can be achieved in a conurbation depends as much upon its domestic and industrial activities as on the environmental protection measures which are enforced. An analytical framework is developed to identify the main relationships between these variables. The framework is used, first, to examine the relationship between population and industrial change and environmental quality in Greater Manchester (England) for the years 1966-76, using published or otherwise accessible data. Large changes are shown to have taken place in the level, composition and spatial distribution of waste generating activities over this period. Data describing these changes are used in conjunction with information relating to waste coefficients and emission factors to explain the main changes in environmental quality that occurred in the conurbation over the period. The analytical framework is then used, in conjunction with economic and population forecasts, to determine likely future changes in population and industrial structure by the mid-1980s and their probable consequences for waste and pollution levels in the conurbation. These preliminary analyses form the basis for the further development of this type of forecasting study, preferably in cooperation with existing planning and environmental control authorities. A two-stage approach to environmental forecasting appears to be the most promising way to proceed. The first stage would produce strategic forecasts for large zones using more readily accessible data and thereby identify environmentally significant areas or activities for further study. The second stage would consist of more detailed studies, involving the collection and analysis of additional survey or cast study material for the areas or activities so identified. SOIL MANAGEMENT AS IT AFFECTS NUTRIENT LOSSES FROM A TROPICAL SOIL IN NIGERIA,
Ibadan Univ. (Nigeria). Faculty of Technology.
G. E. Osuji, and O. Babalola.
Journal of Environmental Management, Vol. 16, No. 2, p 109-116, March, 1983. 6 Tab, 19 Ref.

Descriptors: *Soil management, *Tillage practices, Nutrients, Agricultural runoff, Leaching, Nitrogen, Soil erosion, Water pollution sources, Storm seepage, Fertilizers.

Five tillage treatments, namely bare fallow, no-tillage, local or manual tillage, plowing only, and conventional tillage (plowing and harrowing), were established on runoff plots on an alfisol with a 5% slope in southern Nigeria. The objective was to determine the effects of these tillage practices on nutrient losses in runoff and soil erosion from shallow soils derived from basement complex rocks. Nutrient losses in both runoff and eroded sediments were in the order: bare fallow > pl > conventional > manual > no-tillage. I cases, nitrogen suffered the greatest loss. Nu losses in runoff water were not very high, but relative concentrations in runoff could pose p tial environmental pollution hazards. Lea losses of nitrogen, as shown by higher conce tions of NO3-N in the subsurface or inter- water, were higher than losses in runoff water this may account for the relatively low effici of applied nitrogen fertilizers in tropical soils. no-tillage technique was found to be an effe means of checking loss of nutrients from agr tural land in the tropics. ACTIVE VERSUS PASSIVE WATER QUALI MONITORING PROGRAMS F WASTEWATER DISCHARGES,
Texas Tech Univ., Lubbock. Dept. of Civil En neering.
G. F. Lee, and R. A. Jones.
Journal of the Water Pollution Control Federati Vol. 55, No. 4, p 405-407, April, 1983. 6 R

Descriptors: *Water quality control, *Water m agement, Data acquisition, Monitoring, Water p lution control, Wastewater treatment, Wastewa facilities, Sampling, Hazard assessment.

The first step that should be considered in develo ing cost-effective technically valid, active wa quality monitoring programs is to determine whi aspects of water quality are of concern to a parti ular location, i.e., to what uses the water und study is to be put. A hazard assessment approa should guide both the development of a monito ing program and the interpretation of the result Such an approach allows the physical, chemic and biological characteristics of the water to b considered in light of their potential impact o beneficial uses of the water by man. The wat quality monitoring program should incorpora sampling sites and frequencies and parameters fo measurement that have sound technical justifica tion. It should be flexible enough so that it can b adjusted on the basis of analytical findings, an there should be a short turn-around time betwee sample collection and data review by those respon sible for water quality control at the site. Rigid fixed-station, fixed-period sampling should be re duced and supplemented with special purpose sam pling where needed. Part of the funds availabl should be devoted to toxicity testing as chemica analyses generally do not provide reliable indica tions of water quality impairment. (Baker-IVI)

s: *Land use, *Topography, *Forest , Small watersheds, Suspended sedi- ter quality, Drainage density, Nitrogen, s, chloride, Texas.

riation of five water quality variables zed using composite water samples col- iodically from eight small watersheds sq km) in forested East Texas during 1977 through 1980. Based on 31 observations during the four-year period the average yield of nitrate-nitrite nitrogen (NNN), total kjeldahl nitrogen (TKN), total phosphorus (PO4), chloride (CHL), and total suspended sediment (TSS) were 1.43, 21.96, 3.09, 50.11, and 90.39 ka/ha/yr, respectively. Compared to the water quality standards of the U.S. Environmental Protection Agency (1976) and the Texas Department of Water Resources (1976) for CHL, TSS and NNN, none of the observations exceeded the limits for public water supplies. The study showed that forested watersheds normally yielded stream flow with better quality than that from agricultural watersheds. Watersheds of greater percent of pasture area, mean slope, stream segment frequency, and drainage density produced greater concentrations for these five chemical parameters in water samples. Meaningful equations were developed for estimating mean average yields for each chemical parameter for each watershed with R(2) ranging from 0.77 to 0.96 and standard error of estimates from 17 to 33 of the observed means. THERE IS AN ANSWER TO GROUNDWATER CONTAMINATION,
Calgon Corp., Pittsburgh, PA.
R. P. O'Brien, and J. L. Fisher.
Water Engineering and Management, Vol. 130, No. 5, p 30-36 and 70, May, 1983. 6 Fig, 4 Tab.

Descriptors: *Activated carbon, *Water quality control, *Groundwater pollution, Water treatment, Drinking water, Organic compounds.

Granular activated carbon (GAC) is being increasingly used to treat and purify contaminated groundwater. Results from 31 different operating plants that employ GAC to remove toxic organic compounds from groundwater supplies are detailed. Sources of contamination of the groundwater included leachate from lagoons and dumpsites, industrial accidents and spills, and spills resulting from railroad or truck accidents. Industrial accidents accounted for 22 of the 31 sources. The data clearly demonstrated that ability of GAC to remove a wide range of organic compounds from the water. Trichloroethylene and tetrachloroethylene were the most frequently detected compounds. Experience suggests that the downflow fixed bed is more cost-effective than a pulsed-bed for groundwater treatment. At 22 of the sites, treatment of groundwater prior to carbon adsorption was not required. These contaminated supplies were stable and contained low concentrations of suspended solids which could be removed in the carbon bed without hindering adsorption or creating a high pressure drop. Contact time is a particularly important design parameter for any adsorption system. To improve carbon efficiency where longer contact times are needed, two adsorbers are usually required. Operating costs with GAC treatment are dependent on a number of factors including flow rates, concentration and type of organics, type of applications, sites requirements, timing requirements, and length of the processing project. As expected, the operating costs for GAC treatment was lower in the case of those projects with lower average influent levels of contaminant. (Baker-IVI)

PROTECTIVE PONDS SAVE ECORSE CREEK,
Wade, Trim and Associates, Inc., Taylor, MI.
D. R. Trim.
Water Engineering and Management, Vol. 130, No. 6, p 48-50 and 58, June, 1983. 3 Fig, 1 Tab.

Descriptors: *Sewer systems, *Settling basins, *Combined sewer overflows, Overflow channels, Construction, Water pollution control, Aeration.

Serious combined sewer overflow problems in several Michigan communities have been solved through the institution of two large retention basins, one covered and incorporating a jet aeration system, and one open. The less expensive, the open stormwater basin, was built under a $2,396,576 construction contract and required about 612,000 cu yd of earth excavation along with the installation of a pumping station, 2,000 ft of 8-in to 60-in diameter sewer and 900 ft of relocation water main. A sewer separation project under another contract routes storm water to it through 7,000 ft of 54-in to 132-in diameter reinforced concrete pipe. The enclosed retention basin was built for $6,489,256 as a 530 ft long by 190 ft wide structure extending 25 ft below grade. Up to about 22,000 gpm of the pumping station's capacity can be used to keep solids in the wastewater stored in the basin in suspension. Constructed at the downstream end of the 54-in interceptor that routes combined flows out of the Ecorse Creek basin, the retention structure is designed to go on-line when flows rise above the 14.2 cfs level, storing up to 13 mil gal of wastewater in both of its chambers if necessary. Since its use, basement flooding was eliminated and the pollution of the creek has been drastically reduced. (Baker-IVI)

A CONCEPTUAL FRAMEWORK FOR MEASURING THE BENEFITS OF GROUNDWATER PROTECTION,
Environmental Protection Agency, Washington, DC. Office of Policy Analysis.
R. L. Raucher.
Water Resources Research, Vol. 19, No. 2, p 320-326, April, 1983. 4 Tab, 15 Ref.

Descriptors: *Groundwater protection, *Cost-benefit analysis, Policy making, Groundwater pollution, Waste disposal, Water use, Geohydrology.

There is an increasing concern regarding the contamination of groundwater by hazardous materials. This concern is now being translated into private and public sector initiatives to implement waste disposal and other policies designed to protect groundwater. These activities generate substantial costs; the purpose of this paper is to establish a framework with which to measure the benefits of such efforts to protect groundwater. This benefits framework is based on the premise that the probabilistic value of protection is at least as great as the expected costs of contamination. These costs are shown to be sensitive to a variety of site-specific hydrogeologic and water use factors and general economic parameters. By facilitating benefit-cost comparisons, the framework provided here should help direct groundwater protection resources to their most efficient uses. (Author's abstract)

INCORPORATING THE STOCHASTIC NATURE OF WATER QUALITY INTO MANAGEMENT,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
R. C. Ward, and J. C. Loftis.
Journal of the Water Pollution Control Federation, Vol. 55, No. 4, p 408-414, April, 1983. 1 Fig, 30 Ref.

Descriptors: *Water quality management, *Stochastic process, Hydrologic cycle, Water quality standards, Statistical methods, Sampling, Monitoring, Networks.

Water quality in a stream or river is the result of two primary causal mechanisms: the activities of society, and the natural hydrologic cycle. Water quality management must deal with both, even if it does attempt to control only one - the activities of society. Both mechanisms may be described as stochastic processes in that each, to some degree, is governed by the laws of chance. Thus, water quality, from a broad management perspective, can be considered a random variable. While past water quality management efforts were soundly based on the state-of-the-art knowledge of the time, the new knowledge must now be incorporated into the management structure, or the structure must be modified to reflect the new knowledge. Several of the implications to management of incorporating concepts of water quality hydrology and statistical sampling are reviewed. Water quality standards should be interpreted in relation to probabilistic information derived from a statistically designed and operated, fixed-station monitoring network. (Moore-IVI)

USE OF RECREATION ANALYSIS IN RESOURCE MANAGEMENT: A CASE STUDY,
Massey Univ., Palmerston North (New Zealand). Dept. of Agricultural Economics and Farm Management.
B. S. Harris, and A. D. Meister.
Journal of Environmental Management, Vol. 16, No. 2, p 1117-124, March, 1983. 3 Fig, 2 Tab, 6 Ref.

Descriptors: *Recreation facilities, *Resources management, *Lakes, Resource allocation, Economic evaluation, Cost-benefit analysis, Decision making.

The value of specific recreation sites is often an important consideration in resource management. The aim of recreation analysis is to derive a monetary value for such sites, providing a comparative figure for efficient resource allocation between alternative uses. The paper summarizes a particular recreation analysis carried out on a lake in the North Island of New Zealand. The methodology is based on the accepted travel cost approach which provides an estimation of the consumers' surplus associated with visitation to a public good type recreational amenity. The results of the study are discussed in relation to their usefulness in resource management decision-making and applicability to cost-benefit type economic evaluations. (Author's abstract)

T. R. Harris, and C. T. K. Ching.
Water Resources Bulletin, Vol. 19, No. 2, p 205-210, April, 1983. 1 Fig, 2 Tab, 8 Ref.

Descriptors: *Economic aspects, *Income, *Water use, *Model studies, Regional development, Employment, Nevada.

Tradeoffs between regional economic development and resource use is a question often confronting local decision makers. A resource-interindustry model can be used to depict the interrelationships between regional economic sectors as to household income and/or employment and resource use. A resource-interindustry model was developed for Humboldt and Lander Counties in Nevada which shows the tradeoffs between regional household income (wages, salaries, profits, and rents) and/or employment and water usage. Water income and water employment multipliers can be ranked, enabling decisionmakers to realize sectors which require greatest regional water usage to regional household income and/or employment. REGIONAL VERSUS LOCAL WATER SUPPLY PLANNING,
Corps of Engineers, Baltimore, MD. Baltimore District.
J. E. Crews.
Journal of Water Resources Planning and Management, Vol. 109, No. 2, p 179-185, April, 1983. 2 Fig, 1 Tab.

Descriptors: *Regional planning, *Water supply development, *Metropolitan water management, Cost analysis, Local governments, Water policy, District of Columbia, Metropolitan Washington D.C. area.

The Metropolitan Washington, D.C., area water supply study being conducted by the U.S. Army Corps of Engineers presents an approach in planning for water supplies that can lead to regional management. The challenge, however, rests with the local decision-makers in seeing that a management plan is adopted for the Metropolitan Washington area. Unfortunately, local governments find themselves in a dilemma revolving around the economic and self-sufficient nature of governance. This paper explains how the Metropolitan Washington area has reached a point when new supplies must be developed. The area's supply base is a finite resource where previous independent actions have not caused any serious problems. Now there are obvious advantages in cooperating to develop a regional water policy as well as sharing in the development of cost-effective solutions. (Author's abstract)

THE ENVIRONMENTAL MONITORING PROGRAM FOR THE WATERSHED OF THE GREAT POND AND RICHARDI RESERVOIRS,
Stone and Webster Engineering Corp., Boston, MA.
J. D. Cleggett.
Journal of the New England Water Works Association, Vol. 97, No. 2, p 119-133, June, 1983. 8 Fig.

Descriptors: *Watershed management, *Reservoirs, Water supply development, Groundwater mining, Water shortage, Surface drainage, Groundwater reservoirs, Wetlands, Reservoir evaporation, Massachusetts, Great Pond Reservoir, Richardi Reservoir.

The towns of Braintree, Randolph, and Holbrook in Massachusetts consume water from the Great Pond Reservoir and the relatively new Richardi Reservoir. The water is basically runoff water from a 10 sq mi watershed comprised of four major wetland areas, connected by a system of brooks and rivers. The drought condition existing since the beginning of 1980 has caused a reduction in supply, forcing the town to impose restrictions on the use of water and to prepare emergency plans to augment the supply. Baseline data about the watershed is used to identify adverse changes and to initiate corrective action directed towards maintaining the area in its present or improved condition. Precipitation is measured daily for each 24 hr period, and is used to indicate the present pattern of rainfall. The inflow to the reservoirs is continually measured to indicate how much water is collected, how long it takes the wetlands to drain into the reservoirs, and how much water comes from each collection area. Once it has been determined which rivers are the major sources, clean-up efforts can be concentrated on those first. Daily consumption is also recorded so as to prepare a projection of future demands. Evaporation is calculated daily for each reservoir to aid in determining whether covers over reservoirs will offer significant help. Water quality throughout the watershed is tested monthly and the entire watershed area is inspected monthly. The second aim of the study is to develop a proposed project to increase the source of supply. A project has been presented and work has begun to excavate certain areas of the Richardi Reservoir which it is believed will intersect groundwater below the Reservoir. Estimates indicate the yield from this new source could be as high as 4 million gpd. (Baker-IVI)

WELLESLEY'S WATER PROGRAM PL NING; DEMAND STRATEGY,
Massachusetts Dept. of Public Works, Welle Hills.
M. R. Berdan.
Journal of New England Water Works Ass ation, Vol. 97, No. 2, p 82-89, June, 1983.

Descriptors: *Water demand, *Massachuse Wellesley, Public opinion, Public participat Pricing, Regulations, Seasonal variations, W supply development.

Two so-called 'demand strategies' have been plemented in Wellesley, Massachusetts, aimed keeping water consumption within the same yi as the system, rather than increasing the supply water to meet rising demands. The first strategy seasonal, peak demand pricing and the second citizen education program centered around a su mertime Odd-Even outdoor watering system. Bo strategies stress use of simple, low cost, creat approaches to buy time, improve product relia ity and enhance public image. Wellesley is prim ily a residential community with about 27,0 people in 8,000 homes spread over 10 sq mi. T water supply consists of seven wells and a 143 distribution system with two sets of covered res voirs with a combined storage capacity of million gallons. The system is fully metered, w 75% of the water going to residential custome and 25% to commercial/municipal users. The cu rent supply of 5.2 million gallons a day is n sufficient to meet present and future peak d demands. The seasonal peak demand rate begun June of 1981 creates a sharply inverted season peak demand rate structure for all custome during the period of May through September. Th unit cost for peak summer consumption is substa tially higher than the regular rate, thus serving an effective deterrent against high consumptio The key to the success of citizen education effor is public awareness, public acceptance and suppor and public participation. The results thus f

suggest that the water conservation and strategies can work and their success re- very large and broad based constituency. ategies are easily implemented, with prom- g term implications. (Baker-IVI)

INDEX OF HABITAT DISTURBANCE FOR LAKESHORE COTTAGE DEVELOPMENT,
Ontario Ministry of Natural Resources, Toronto. Wildlife Branch.
G. Racey, and D. Eueler.
Journal of Environmental Management, Vol. 16, No. 2, p 173-179, March, 1983. 4 Fig, 2 Tab, 18 Ref.

Descriptors: *Land use, *Land development, Habitats, Environmental effects, Lake shores, Vegetation effects, Runoff, Water quality.

An index is identified that can be used to quantify habitat changes resulting from lakeshore cottage development. Characteristics of cottage lots in central Ontario are also discussed. An Area Development Index (ADI) was calculated using variables obtained from the area disturbed in the ground, shrub, and tree layers. The area of disturbed habitat in the three vegetation layers varied significantly ($p<0.01$) with lot size, and the area cleared in the shrub layer was significantly larger ($p<0.05$) than that cleared in the ground or tree layer. The mean number of buildings on a lot was 2.2 (+ or - 0.9), and their mean distance from the water was 20.0 m (+ or - 12.3). These differences were not significant. Small lots (<0.2 ha) can be expected to have a large ADI value. As the lot size increases there is an expected increase in the amount of undisturbed area on the lot. The major factor affecting wildlife, runoff, or water quality is not usually the presence of the cottage itself, but the residents activities and the destruction of habitat associated with cottage construction. The defined relationship between lot size and the ADI makes it possible to predict the proportion of area disturbed by development. (McKeon-IVI)

TEMPERATURE DISTRIBUTION AROUND A WELL DURING THERMAL INJECTION AND A GRAPHICAL TECHNIQUE FOR EVALUATING AQUIFER THERMAL PROPERTIES,
D'Appolonia Consulting Engineers, Inc., Pittsburgh, PA.
C.-S. Chen, and D. L. Reddell.
Water Resources Research, Vol. 19, No. 2, p 351-363, April, 1983. 13 Fig, 2 Tab, 43 Ref.

Descriptors: *Thermal injection, *Heat transfer, Confined aquifers, Conduction, Convection, Mathemetical models, Thermal conductivity, Caprock, Injection wells.

Analytical solutions of temperature distribution are developed for the problem of thermal injection into a confined aquifer with a caprock of finite thickness. Heat transfer by horizontal conduction and convection within the aquifer and by vertical conduction in the caprock and bedrock is considered. Steady state and two asymptotic unsteady state solutions of temperature distribution around a thermal injection well are determined. One unsteady state solution is for short time periods and the other is for long time periods. The caprock thickness is only important in the long time period solution. A graphical technique is presented using hypothetical data for evaluating four pertinent aquifer thermal properties: (1) the horizontal thermal conductivity of the aquifer, (2) the thermal capacity of the aquifer, (3) the vertical thermal conductivity of the caprock, and (4) the thermal capacity of the caprock. Field measurements of aquifer temperatures near the steady state condition are theoretically needed to utilize the graphical technique. In many practical situations a long time period is required to achieve a steady state condition. Therefore, a modified graphical technique employing an unsteady temperature distribution is illustrated and can be used to estimate the horizontal thermal conductivity and aquifer thermal capacity. APPLICATION OF NETWORK DESIGN PROCEDURES FOR REDESIGNING KIZILIRMAK RIVER BASIN RAINGAUGE NETWORK, TURKEY,
Middle East Technical Univ., Ankara (Turkey). Dept. of Civil Engineering.
U. Sorman, and G. Balkan.
Hydrological Sciences Journal, Vol. 28, No. 2, p 233-246, June, 1983. 6 Fig, 2 Tab, 12 Ref.

Descriptors: *Rain gages, *Network design, Rainfall distribution, *Turkey, Hydrologic data, Kizilirmak River basin.

Recently developed rainfall network design techniques are discussed and compared. Present day hydrological studies require high levels of accuracy from collected data. Also, scientists need to know the degree of accuracy of the information they use. The existing rainfall network in the Kizilirmak basin must be redesigned in order to meet the required level of accuracy preset by rainfall data users. The three following techniques were applied: optimum interpolation procedure which is a flexible method; variance of mean areal rainfall; and the analysis of variance. The existing network of 52 gauges is redesigned so that the network will have an average root mean square error (rmse) of < 32 mm and the percentage of the area with rmse > 36 mm is limited to 10%. The proposed criteria are satisfied by a network of 53 gauges of which eight were newly established and seven of the existing ones removed. (Author's abstract)

GROUNDWATER OBSERVATION NETWORK DESIGN FOR THE KANSAS GROUNDWATER MANAGEMENT DISTRICTS, U.S.A.,
Kansas State Geological Survey, Lawrence.
M. Sophocleous.
Journal of Hydrology, Vol. 61, No. 4, p 371-389, 1983. 9 Fig, 1 Tab, 13 Ref.

Descriptors: *Network design, *Groundwater level, Observation wells, Groundwater management, Water table, Economic aspects, Kansas.

Concerns about the efficiency and economic soundness of the Kansas groundwater monitoring program led to a systematic redesign of this network, a tentative phase of which is presented in this study. The objectives of this paper include monitoring of major aquifers within each groundwater management district at a spatially more uniform level of accuracy, elimination of redundant measurements and optimization of the information gained from each observation well. The theory of regionalized variables is employed to estimate the amount of spatial variability of the water table, on which the network design is based. This study shows that it is not practical to attempt to reduce the already existing level of uncertainty uniformly throughout the various districts; to do so would tremendously increase the cost of well monitoring, which is already very high. Assuming that the currently existing network is satisfactory for the State's objectives, a reduced network consisting of one well every 6.4 km is equally satisfactory. The reduced network yields district-wide maps that do not differ significantly from those produced using the present network and at the same time it reduces the already-existing network by 18-47%. Therefore, adoption of a rearranged square well network is recommended, which is reduced to a 6.4-km spacing to achieve both a uniform level of information about the water table and a minimum required accuracy. ORGANIZATIONAL NEEDS FOR HYDROLOGICAL APPLICATIONS OF SATELLITE REMOTE SENSING IN DEVELOPING COUNTRIES,
Bristol Univ. (England). Dept. of Geography.
E. C. Barrett.
Hydrological Sciences Journal, Vol. 28, No. 2, p 273-281, June, 1983. 2 Tab, 9 Ref.

Descriptors: *Remote sensing, *Satellite technology, *Hydrologic data, *Rainfall, Institutional constraints, Political constraints, *Developing countries.

Remote sensing has great, but largely unrealized, potential in operational hydrology especially in countries where conventional data are not adequate even to meet existing needs. It is argued that organizational, not physical, problems have been the most significant in limiting the spread of satellite remote sensing applications for hydrology within the developing world. Looking to the future, the relative merits of tactical ('bottom up') and strategic ('top down') approaches for the promotion of satellite remote sensing for hydrology in such areas are outlined and discussed. Existing and proposed International Hydrological Program projects may proffer some suitable channels through which significant progress could be made. (Moore-IVI)

Descriptors: *Weather forecasting, *Satellite technology, Midwestern United States, Moisture profiles, Storms, Model studies, Remote sensing, Forecasting, Prediction, Model testing.

Sub-synoptic resolution satellite-derived temperature and moisture profiles have been assimilated into a mesoscale numerical weather prediction model. This model is intended for use in forecasting the environment of organized convective storm complexes in the midwestern section of the United States. The domain of the analysis covers most of the North American continent, as well as adjacent areas of the Atlantic and Pacific Oceans. The scheme uses a combination of the successive correction method (SCM) of Cressman and the variational blending techniques of Sasaki. Two characteristics make it particularly suitable for the objective analysis of satellite temperature profiles: the geopotential thickness is a primary analysis variable, making it a wind from mass scheme, and secondly, differing weight can be given to scalar and gradient geopotential information during the variational blending procedure, thus allowing the geopotential gradient information inherent in the satellite temperature data sets to be used more effectively. Assimilation of high horizontal resolution satellite temperature data sets into a mesoscale numerical weather prediction model produced short term forecasts with a promising level of skill. The forecasts show a good level of accuracy as compared with high resolution rawinsonde data. The high horizontal resolution of the satellite data contributes to the accuracy of the forecast through the model's ability to retain details of the initialization. (Baker-IVI)

EVALUATION OF A DEPTH PROPORTIONAL INTAKE DEVICE FOR AUTOMATIC PUMPING SAMPLERS,
Pacific Southwest Forest and Range Experiment Station, Arcata, CA.
R. E. Eads, and R. B. Thomas.
Water Resources Bulletin, Vol. 19, No. 2, p 289-292, April, 1983. 3 Fig, 5 Ref.

Descriptors: *Intakes, *Water sampling, *Suspended sediments, Pumps, Water depth, Sampling.

A depth proportional intake boom for portable pumping samplers was used to collect suspended sediment samples in two coastal streams for three winters. The boom pivots on the stream bed while a float on the downstream end allows debris to depress the boom and pass without becoming trapped. This equipment modifies point sampling by maintaining the intake nozzle at the same proportion of water depth regardless of stage. Data taken by pumping samplers with intakes mounted on the boom were compared with depth integrated hand samples. Pumped samples showed higher concentrations than depth integrated hand samples. Results suggested that cross-sectional sampling can give high precision with proper placement and calibration of a boom mounted intake. (Author's abstract)

EFFECTIVE USE OF LANDSAT IN HYDROLOGIC MODELS,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
A. Rango, A. Feldman, T. S. George, III, and R. M. Ragan.
Water Resources Bulletin, Vol. 19, No. 2, p 165-174, April, 1983. 4 Fig, 5 Tab, 10 Ref.

Descriptors: *Hydrologic models, *Discharge frequency, *Satellite technology, *Cost analysis, Hydrologic cycle, Data interpretation, Land use, Remote sensing, Watersheds.

In a cooperative demonstration project, NASA and the U.S. Army Corps of Engineers (Corps) compared conventional and Landsat-derived land-use data for use in hydrologic models, and the resulting discharge frequency curves were analyzed. When a grid-based data-management system was used an a cell-by-cell basis (size about 1.1 acres or 0.45 hectare), Landsat classification accuracy was only 64%, but, when the grid cells were aggregated into watersheds, the classification accuracy increased to about 95%. When both conventional and Landsat land-use data were input to the HEC-1 model for generating discharge frequency curves, the differences in calculated discharge were judged insignificant for subbasins as small as 1.0 sq mi (2.59 sq km). For basins larger than 10 sq mi (25.9 sq km), use of the Landsat approach is more cost-effective than use of conventional methods. Digital Landsat data can also be used effectively by local and regional agencies for hydrologic analysis by incorporating the data into grid-based data-management systems. The transfer of this new technology is well under way through inclusion in some Corps training courses and through use by both county government personnel and private consultants. (Author's abstract)

AL WATER-USE INFORMATION
AM,
al Survey, Reston, VA.
ann, IV, J. E. Moore, and E. B. Chase.
f Water Resources Planning and Manage-
ol. 109, No. 2, p 186-194, April, 1983. 5

Descriptors: *Water use, *Information systems, *Data collections, Computers, Ground water, Surface water, Saline water, Consumptive use, Data acquisition, Data interpretation.

The National Water-Use Information Program is a cooperative program between the states and the Federal Government. The purpose of the program is to determine how much fresh and saline surface water and ground water is withdrawn and for what purpose, how much water is consumed during use, and how much water is returned to a water body (stream, lake, or aquifer) after use. To accomplish its purpose, the program's goals are to: (1) collect and compile water-use data; (2) develop and refine computerized water-use data systems at both the state and national levels; (3) devise new methods and techniques to improve the collection and analysis of water-use information; and (4) disseminate this information to those involved in establishing water resources policy and to those managing the resource. The program was established in 1977, when the Congress of the United States recognized the need for uniform information on water use and directed the U.S. Geological Survey to establish a program to complement the Survey's data on the availability and quality of the Nation's water resources. CONSIDERATION OF THE UPLIFT PRESSURE OF WATER IN CALCULATIONS OF THE STABILITY OF CONCRETE DAMS ON ROCK FOUNDATIONS,
Yu. A. Fishman.
Hydrotechnical Construction, Vol. 16, No. 9, p 502-507, September, 1982. 4 Fig, 1 Tab, 9 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 9, p 41-44, September, 1982.

Descriptors: *Dam design, *Dam foundations, *Uplift pressure, *Concrete dams, Dam stability, Rock foundations, Stability analysis, Dam safety.

It has been suggested that the coefficient of effective area of uplift on the bottom of concrete structures (alpha 2) is different in the prelimit and limit states of structures due to the fact that in the limit state, the foundation receives disturbances such that the bounds are ruptured, crack open, and the area of contact on the surface of failure decreases. Consideration of the total of uplift, which corresponds to a state of limit equilibrium, in calculations of the stability of concrete structures of rock foundations is inadmissible and leads to results contradicting dam design and operating practice. Correct consideration of uplift and a substantial decrease of the value of the coefficient alpha 2 makes it possible to obtain higher values of the stability factors of concrete dams or to achieve for the same reliability a decrease of their cost. The coefficient of effectiveness of transmitting uplift alpha 2 under various conditions should be studied. (Moore-IVI)

CALCULATION OF LININGS OF A SYSTEM OF PARALLEL ROUND TUNNELS,
N. N. Fotieva, G. Ya. Gevirts, A. K. Petrenko, and A. N. Kozlov.
Hydrotechnical Construction, Vol. 16, No. 9, p 520-525, September, 1982. 3 Fig, 2 Ref. Translated from Gidrotekhnicheskoe Stroitel'sfvo, No. 9, p 53-56, September, 1982.

Descriptors: *Tunnel construction, *Pressure, *Tunnel linings, Construction, Design criteria, Powerplants, Elastic properties, Linings, Tunnels.

A method for calculating linings of two identical, mutually influencing parallel round tunnels for the action of an internal pressure based on the solution of the two-dimensional problem of elasticity theory for a medium weakened by two identical supported holes has been generalized to the case of an arbitrary number of parallel round tunnels, with centers on the same line, which can have different diameters and linings of different thicknesses made of different materials. The proposed method of calculation was used by the Leningrad Branch of the All-Union Planning, Surveying, and Scientific Research Institute when developing the specifications of tunnels for one of the hydrostations. Results of calculations are given for the section near the powerhouse (five parallel tunnels) in the construction and operating periods. The moduli of deformation of the concrete for two loaded linings were assumed reduced with consideration of the formation of cracks. Three variations of the pressures were examined for calculating the linings in the operating period. The same method can be further generalized to the case when the centers of the tunnels do not lie on the same line. (Baker-IVI)

THE CARSINGTON SCHEME - RESERVOIR AND AQUEDUCT,
P. G. Davey, and P. G. Eccles.
Journal of the Institution of Water Engineers and Scientists, Vol. 37, No. 3, p 215-239, June, 1983. 6 Fig, 3 Tab.

Descriptors: *Water supply development, *Reservoirs, *Aqueducts, *Pumped storage, *England, Reservoir design, Earth dams, Gravity flow, Flow augmentation.

The Carsington reservoir scheme is being developed to increase the water resources of the Severn-Trent Water Authority in the East Midlands, England. During the winter periods, water will be abstracted at the Ambergate pumping station and pumped to Carsington reservoir. In dry weather, when there is insufficient flow in the river to meet increased demand, water will be released from the reservoir and will flow by gravity to Ambergate where it will return to the river by way of the existing intake works. Water for north-east Derbyshire will be taken at Ambergate via Ogston reservoir and for the rest of the area, at Little Eaton. Provision has also been made to discharge water from the reservoir to the river Dove to augment flows to the Dove reservoirs as necessary. The dam site is unsuitable for any form of concrete dam due to the depth required for the foundations to be in unweathered strata, but is well suited for an earthfill dam, using local clays and shales. An aqueduct 10.5 km long, nearly all in tunnel, will connect the reservoir and the river Derwent. The tunnel will have a diameter of 2.3 m and will be lined with smooth bore reinforced concrete segments. The tunnels are needed to reduce the pumping head and the land disturbance and to permit gravity flow back to the river. (Moore-IVI)

Many engineering designs for water supply networks represent extensions to existing systems, so the determination of accurate estimates of the parameters for use in a mathematical model may be difficult since in some places a considerable deviation from newly constructed conditions develops. First order analysis (FOA) principles were used to examine the sensitivity of the pressure differential across several pipes due to uncertainties in the mathematical model, diameter, discharge, hydraulic exponent, and the Hazen- Williams coefficient. This information can be used to identify when considerable uncertainty exists in estimation of the pressure drop across a pipe and thus is an indication of whether a field-testing program may be warranted. The results obtained were also used to obtain an indication of the required accuracy of measurement devices for providing meaningful results in field measurements of pressure differentials along sections of distribution mains. MANHOLE INFLOW AND INFILTRATION STOPPED WITH SPECIAL REPAIRS,
Driver, Olson-Degraff and Associates, Rockford, IL.
F. T. Driver.
Water Engineering and Management, Vol. 130, No. 4, p 31-32, April, 1983.

Descriptors: *Infiltration rate, *Sewer infiltration, *Manholes, Sealants, Grouting.

Relatively new methods of manhole rehabilitation have substantially and economically reduced inflow and infiltration into the sewer collection network of Northbrook, Illinois. Damaged or poorly fitting manhole lids were replaced. Interior manhole restoration included replacing loose brick and mortar. Interior surfaces in the system were cleaned by high-pressure water jets. A chemically active cementitious material was applied to masonry surfaces to reduct further outflow. In those manholes where leaks were relatively few, pressure-grouting was used. Chemical grouting of precast structures, waterproofing of older brick structures, and lid repairs on just 170 of the village's manholes have reduced the total system infiltration and inflow by as much as 10%. DETERMINATION OF THE CROSS SECTION OF CANAL CHANNELS FOR SEDIMENT TRANSPORT,
Kh. Sh. Shapiro.
Hydrotechnical Construction, Vol. 16, No. 9, p 498-501, September, 1982. 2 Tab, 5 Ref. Translated from Gidroteckhnicheskoe Stroitel'stvo, No. 9, p 38- 40, September, 1982.

Descriptors: *Canals, *Channels, *Sediment transport, *Silting, Slopes, Channel morphology, Discharge capacity, *USSR.

A formula for selecting the slope and cross sections of a canal channel which provides passage of the design water discharges, dynamic stability of the channel, and sediment transport is given in two forms. One is for those cases when charging of the flow with fine sediment fractions is considerably below its transport capacity, which occurs in a considerable majority of canals with an intake from the Amu Darya, Syr Darya, Kura, and other rivers. The other method is for those relatively rare cases when the flow entering the canal is charged in excess of the transport capacity with all fractions, such as the Tedzen River. The slopes obtained by using this formula, especially in the case of large discharges, are slightly less than the slope in the water source. Nonsiltation of canals when the slopes are less than the river slope is confirmed by data from the Sukkur hydrodevelopment (Moore-IVI)

At the 19th Congress of the International Association of Hydraulic Research, 72 reports were offered at session D, Hydraulic Research and Modeling Techniques. The papers fitted into the following categories: criteria of correspondence of model and prototype; modeling in the case of several characteristic dimensionless numbers, e.g. Froude and Reynolds; new laboratory modeling techniques; new achievements in the area of instruments for laboratory and prototype investigations; and digital and analog computers as laboratory equipment. The problem of combining hydraulic (physical) and numerical modeling in hydraulic research was examined, bearing in mind that in both cases reference is to the solution of the problem by the modeling method with the use of different means. The selection of the modeling method in each specific case is determined by many circumstances, with the basic limitations of the possibility of their use being paramount. Attention was also given to the correspondence of the roughness of the stream channel on the model and prototype and to a problem related to distortion of the geometric scales. The effect of Re number on the discharge characteristic of a measuring flume was reported. The selection of the time scale of channel deformations and schematization of a transient hydraulic regime were studied. Cavitation erosion, groundwater flow measurements, discharge of warm water, new measuring instruments and methods, and use of a digital computer as a means of controlling an experiment were each reported on at the conference. A list of session D reports and authors is provided as an appendix to the review. (Baker-IVI)

EXWICK FLOOD RELIEF CHANNEL HEADWORKS,
M. C. Harries.
Journal of the Institution of Water Engineers and Scientists, Vol. 37, No. 3, p 243-250, June, 1983. 4 Fig, 1 Ref.

Descriptors: *Flood control, *Radial gates, *Bed load, Channels, Hydraulic design, Flow controls, Model studies, Accretion.

The Exeter Flood Protection Scheme was promoted in the early 1960s to protect the low lying parts of the city from a recurrence of the serious floods of 1960. A design was developed for the works at the head of the relief channel which controlled the distribution of flow between the river channel and the relief channel. Model studies indicated that when the flood flow was at the estimated formative discharge, 3,700 cusec would be discharged to the relief channel, leaving only 4,300 cusec in the river channel downstream from the headworks. The whole of the bed load would probably remain in the river channel, but the greatly reduced flow would be unable to carry it forward, and considerable accretion would take place. The capacity of the river channel could be increased to 9,000 cusec by raising the right bank. Calculations showed that a structure consisting of a central unrestricted flume 32 ft wide flanked on each side by a radial gate 34 ft wide could be operated to give the ideal distribution of all flows up to the design flood. The headworks have been constructed in accordance with the design and have operated up to about half the design flood. (Moore-IVI)

cs, Physicochemical processes, Sedi-
ort, *Shoaling processes.

ion processes in our nation's waterways
s are controlled by a complex array of
d chemical factors that are known only
terms. Evaluation of hydrodynamic
nd identification of null points are the
methods in predicting shoaling in navi-
nnels. Physicochemical processes con-
limentation are complex interactions of
solids and water chemistry which are in
ages of infancy in respect to our under-
nd interpretation. Because the bulk of
e dredging occurs in estuaries, and since
ocess concepts for estuaries can be ap-
stream and coastal areas, this study is concentrated on the shoaling processes common to estuaries. The estuary itself is a major source of shoaling material, perhaps even the primary source in many cases. Estuaries are sediment traps that are gradually filling with sediment. Manmade modifications can dramatically alter shoaling patterns by changing either the depositable sediment supply or the transport capacity. (Moore-IVI)

SEDIMENT SUSPENSION WITH RIPPLED BED,
Saitama Univ. (Japan). Dept. of Foundation Engineering.
S. Ikeda, and T. Asaeda.
Journal of Hydraulic Engineering, Vol. 109, No. 3, p 409-423, March, 1983. 13 Fig, 3 Tab, 11 Ref.

Descriptors: *Ripple marks, *Sediment suspension, *Turbulent flow, Vortices, Entrainment, Model studies, Eddies, Water currents, Statistical analysis.

Experiments on the suspension of sediment were performed in a flume with and without a sediment layer on the bottom. For movable bed runs, three-dimensional sand ripples were found to seriously affect the features of the suspended sediment. The horseshoe vortices and the resulting bursts in the lee of the ripples intermittently entrain a large amount of sediment into the outer layer of flow. Details of the suspension process were studied using a sand ripple model made of plaster. The result revealed that the vertical component of turbulent eddies is responsible for the suspension of sediment, and that the component is statistically described by the Gaussian distribution. The statistical distribution of the concentration fluctuation was observed to be highly skewed, and the reason was determined to be the fact that the concentration increases to the power of eight against the vertical fluid velocity. The period of the intermittent ejection of sediment agreed reasonably with those reported for natural geophysical flows. Thus, the suspension of sediment in flows with rippled beds was proven to be significantly correlated with bursting phenomenon behind sand ripples. (Moore-IVI)

DIFFERENCE METHODS OF FLOW IN BRANCH CHANNEL,
Academia Sinica, Shanghai (China). Shanghai Inst. of Computer Technology.
Z.-C. Li, L.-J. Zhan, and H.-L. Wang.
Journal of Hydraulic Engineering, Vol. 109, No. 3, p 424-446, March, 1983. 11 Fig, 7 Ref.

Descriptors: *Unsteady flow, *Branch channels, Tidal rivers, Flow characteristics, Channels, Flood flow, Mathematical studies, Hydraulic equations, *Yangtse River Branch Channel.

With the development of river transportation and water conservation construction, unsteady flows in branching channels need to be calculated frequently. A study was made of the methods of calculation. In order to compute the unsteady flow in a channel without branching, non-equidistant difference schemes on interior mesh points and the corresponding difference schemes on boundary mesh points have been developed. The branching of channels is a usual natural phenomenon. The Stoker method can be applicable only to the simple circumstance when the branch-point is basically stationary. In fact, the branch point of tidal river (or some inland rivers) is movable within a somewhat large area depending on the variation of tide height (or flood height). For the movable branch point, implicit and semi-implicit methods are provided. Both methods have already found their use in practical problems. (Moore-IVI)

UNIFORM REGION OF SELF-AERATED FLOW,
Canterbury Univ., Christchurch (New Zealand).
I. R. Wood.
Journal of Hydraulic Engineering, Vol. 109, No. 3, p 447-461, March, 1983. 11 Fig, 14 Ref.

Descriptors: *Spillways, *Aeration, Slopes, Velocity, Entrainment, Friction, Air concentration.

The measurement of air concentration and velocity obtained in the laboratory are compared with the recent prototype measurement obtained on Aviemore spillway. This comparison suggests that if a characteristic depth such as the depth at which the air concentration is 0.9 is chosen then the averaged air concentration over this depth is only a function of the slope. Similarly the air concentration distribution is also determined by the slope. The velocity distribution determined in the laboratory and in the field are also compared and it is suggested that water velocity measurements are consistent with a universal velocity distribution. These with the Darcy friction factor computed from laboratory results lead to a simple method for predicting the design parameters in the uniform aerated flow at the end of a long spillway. FLOW NEAR GROIN-LIKE STRUCTURES,
Alberta Univ., Edmonton. Dept. of Civil Engineering.
N. Rajaratnam, and B. A. Nwachukwu.
Journal of Hydraulic Engineering, Vol. 109, No. 3, p 463-480, March, 1983. 8 Fig, 1 Tab, 16 Ref.

Descriptors: *Groins, *Turbulent flow, *Hydraulic models, Velocity, Deflection, Flow control, Model studies, Shear stress.

This paper presents the results of an experimental study on the structure of turbulent flow near groin-like structures. Based on experimental observations, the deflected flow has been analyzed using the model of the three-dimensional turbulent boundary layer. The flow bounded by the separating stream line, the groin, and the adjacent bank has been analyzed by treating it as a shear layer in which the velocity profiles have been found to be similar. The amplified bed shear stress near the groin has also been analyzed using the similarity idea. Even though the majority of the present experiments were done with the thin-plate groin, some observations were also made on a groin with a semicylindrical nose. (Author's abstract)

CLEAR-WATER SCOUR AT CYLINDRICAL PIERS,
Auckland Univ. (New Zealand).
A. J. Raudkivi, and R. Ettema.
Journal of Hydraulic Engineering, Vol. 109, No. 3, p 338-350, March, 1983. 8 Fig, 1 Tab, 8 Ref.

Descriptors: *Piers, *Scour, *Particle size, Bridges, Sediment transport, Bed sediment, Sediment erosion.

The results of laboratory experiments on the clear-water local scour of cohesionless bed sediment at cylindrical bridge piers are presented. The equilibrium depth of clear-water local scour is related to the grading of the bed sediment. In general, as the geometric standard deviation of the particle size distribution increases, the equilibrium scour depths decrease. The equilibrium depth of local scour decreases with the decreasing relative size of pier diameter to mean bed particle size for values less than about 20 to 25. The maximum equilibrium depth of clear-water local scour is a function of the relative depth (depth of flow/pier diameter) and the relative size (pier diameter/mean particle size). The equilibrium depth of local scour decreases at a greater rate with decreasing flow depth for smaller values of the relative flow depth. The decrease in the equilibrium depth is caused by to the interference of the water surface roller formed around the pier with the downwards flow into the scour hole. (McKeon-IVI)

CHANNEL MIGRATION AND INCISION ON THE BEATTON RIVER,
Wollongong Univ. (Australia). Dept. of Geography.
G. C. Nanson, and E. J. Hickin.
Journal of Hydraulic Engineering, Vol. 109, No. 3, p 327-337, March, 1983. 6 Fig, 1 Tab, 7 Ref.

Descriptors: *Bend migration, *Channel migration, Channel erosion, Flood plains, Forest succession, Channel width, Beatton River, *British Columbia.

New field data relating to bend migration rates with bend radius of curvature to channel width ratios (r sub m /w) for the Beatton River in British Columbia confirm the form of the relationship previously described, although there is more variance than initial results suggested. Recent data from forest successions on the floodplains of a variety of migrating rivers show that channel migration is a discontinuous process within any single bend. This means that predictions of migration rates for individual bends, based on short-term measurements using erosion pins or aerial photographs, are highly suspect. These variations in migration rate are likely a response to fluctuating channel widths over time because of a short-term imbalance between the rate of cutbank erosion and the rate of point-bar sediment accumulation. Finally the examination of new evidence of channel incision on the Beatton River shows that the river is downcutting at a rate of about 2 mm/yr, not at 10 mm/yr as reported earlier. (Moore-IVI)

WAVES IN MEANDERING STREAMS,
Michigan Univ., Ann Arbor.
C.-S. Yih.
Journal of Fluid Mechanics, Vol. 130, p 109-121, 1983. 2 Fig, 9 Ref.

Descriptors: *Wave propagation, *Stationary waves, Meanders, Spillways, Open channels, Froude number, Free surfaces, Mathematical models, Water depth.

Open water transport channels in mountainous regions often wind along contour lines of the terrain, and it has been observed that at a certain speed of flow waves of large amplitude form. Also, at the entrance of dam spillways, the contraction may create violent diamond pattern waves. Hence waves in meandering streams or in channels of variable width are of practical importance. Free-surface and internal stationary waves in a meandering stream are treated, and analytical solutions given. For each category there is an infinite number of Froude numbers, depending on the wavenumber of the meander, at which resonance occurs, and the amplitude of one of the wave components becomes infinite, according to the linear theory. These critical Froude numbers are interpreted physically. Variable depth is treated for the case of free-surface waves, and it is shown how the eigenvalues of a singular differential equation can be found under the requirement that the eigenfunction be non-singular. An attempt is made to explain the self-induced, non-stationary waves in water flowing between corrugated vertical walls, by an instability mechanism previously proposed. There is strong evidence that this mechanism is at work, at least when a sloshing mode is involved in the wave-triad interaction. (Moore-IVI)

STEADY SHALLOW FLOW OVER CURVED BEDS,
Asian Inst. of Tech., Bangkok (Thailand).
N. S. Sivakumaran, T. Tingsanchali, and R. J. Hosking.
Journal of Fluid Mechanics, Vol. 128, p 469-487, 1983. 12 Fig, 3 Tab, 11 Ref.

Descriptors: *Shallow flow, *Bed curvature, Critical flow, Froude number, Steady flow, Model studies, Mathematical models, Free surfaces, Bed pressure.

The validity of recent shallow-flow equations with bed curvature is examined. Subcritical, critical and supercritical steady-flow solutions are identified, and the point of critical flow on the bed located, in terms of a generalized Froude number. Experiments on steady flow over both a symmetric and unsymmetric bed profile show that the theory satisfactorily predicts the free-surface and bed-pressure profiles over -2 < or approximately = kh < or = 0.54 (where k is the bed curvature and h is the flow depth normal to the bed). SETTLING QUIETS THE STORM EFFECTS,
Finkbeiner, Pettis and Strout Ltd., Toledo, OH.
G. G. Nixon, and G. L. Hoffman.
Water Engineering and Management, Vol. 130, No. 4, p 29-30, April, 1983.

Descriptors: *Clogging, *Filter media, *Storm water, *Silt load, Ohio, Water treatment facilities, Clarification, Lake Erie, Sedimentation basins.

On December 2, 1974, a severe storm swept across Sandusky, Ohio, on the south shore of Lake Erie. Sediment-laden runoff waters clogged the treatment facility, and the runs for the 12 filters were reduced to three hours. As a result of this occurrance, Sandusky began the construction of pre-sedimentation basins or tanks. Two aluminum dome-covered above-ground pre-sedimentation basins or tanks, each with a 100 foot inside diameter and providing 18 feet of water depth, were constructed. A three story Quick Mix building was built between them. Water is now pumped from the lake to this structure by a new variable frequency vertical turbine pump and an older, previously installed variable-speed pump, each with a capacity of 11.25 mgd. Raw lake water is flash-mixed with liquid alum in the Quick Mix facility and then transferred to the pre-sedimentation basins. These basins, operating in parallel, are of the flocculator-clarifier type, and additional mixing takes place within their skirts. Sludge settles to the bottom of the tanks and is discharged into sludge lagoons on the treatment plant site. The clarified water flows by gravity to the plant for further sedimentation and filtration. Now, during storm events when turbidity becomes extremely high, much of the excess solids immediately drop into the pre-sedimentation tanks, thus preventing the existing water treatment and filtration plant from being clogged. In addition, the media in six of the 12 existing filters was replaced. The pre-sedimentation project was completed in 1980, 26 months after construction began, at a total cost of 2.6 million dollars. WAYS TO INCREASE THE EFFICIENCY AND RELIABILITY OF OPERATING HYDROELECTRIC STATIONS WITH MULTIPURPOSE RESERVOIRS,
M. P. Fedorov.
Hydrotechnical Construction, Vol. 16, No. 9, p 479-483, September, 1982. 3 Fig, 1 Tab, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 9, p 16-18, September, 1982.

Descriptors: *Reservoir operation, *Multipurpose reservoirs, *Hydroelectric plants, *Multivariate analysis, *Competing use, Water use, Long-term planning, Water management.

The operating regimes of hydroelectric stations with multipurpose reservoirs undergo considerable changes with time, which should be taken into account during design. In practice, it is very complicated to assess the changes in the regimes of water resources use for a particular reservoir more than 5-10 yr in the future. At present, about 20-25% of the installed capacity at hydroelectric stations is not used for a number of reasons, including 8-10% due to unplanned nonpower use in water-management systems. Intensification of nonpower water use substantially restricts the regimes of water energy use at stations with multipurpose reservoirs. It is necessary to conduct broad investigations of prospective operating regimes of such hydroelectric stations based on a multifacto sis of the water use conditions. It is expec examine new prospective operating regime at improving the quality and reliability power supply with the use of the installed c under conditions of reduced firm output fro tipurpose reservoirs. Technical and econom stantiation of prospective regimes should be on the development of organizational and te measures to maintain and provide reliabili efficiency of operation of the hydroelectric under more complex conditions of ope (Moore-IVI)

GAL MODELING OF TRANSIENT OW,
neer Waterways Experiment Station, MS.
ll, and H.-Y. Ko.
Geotechnical Engineering, Vol. 109, 6-555, April, 1983. 11 Fig, 5 Tab, 15

Descriptors: *Model studies, *Earthworks, *Embankments, *Flow, Pore pressure, Drawdown, Headwaters, Transient flow, Flow rates.

The phenomenon of transient water flow in earth embankments is examined. State-of-the-art solution techniques and their shortcomings are outlined. It is hypothesized that better solutions are obtainable through centrifugal modeling of the process. An experimental program is described. In order to interpret the experimental results, theoretical scaling relations for quantities pertinent to transient water flow are developed through consideration of the basic independent variables governing the flow. Testing was conducted on a geotechnical centrifuge in a container specially constructed for the test series. Acceleration levels of 25 g, 37.5 g, and 50 g were used. Pore pressures were measured and recorded during the transient rise and fall of the headwaters by four miniature pressure transducers. From these data, histories of total head as a function of time and equipotentials during headwater rise and drawdown are plotted. Steady state flow rates are also measured. Analysis of the data leads to the conclusion that theoretical scaling relations are valid and that this method does indeed give a better understanding of the phenomenon of transient flow and may be useful in design practice. LIQUEFACTION SITES, IMPERIAL VALLEY, CALIFORNIA,
Geological Survey, Menlo Park, CA.
T. L. Youd, and M. J. Bennett.
Journal of Geotechnical Engineering, Vol. 109, No. 3, p 440-457, 13 Fig, 1 Tab, 16 Ref.

Descriptors: *Liquefaction, *Earthquakes, *Sand, Soil types, Sediments, Sand boils, Channels, Earthquake engineering, Soil physical properties, California, Imperial Valley.

Sands that did and did not liquefy at two sites during the 1979 Imperial Valley, California, earthquake (magnitude 6.6) are identified and their properties evaluated. From cone soundings, stratigraphy was determined, soil types and properties estimated, and optimal locations for samples and standard penetration tests (SPT) selected. Samples were used to classify sediments and to identify modes of deposition. SPT tests were used to evaluate liquefaction susceptibility. Loose fine sands in an abandoned channel liquefied and produced sand boils, ground fissures, and a lateral spread at the Heber Road site. Evidence of liquefaction was not observed over moderately dense over-bank sand east of the channel nor over dense point-bar sand to the west. Standard analyses predict that both the channel and the over-bank sands are liquefiable, but that the point bar is resistant. At the River Park site, a layer of loose floodplain silty sand overlies a layer of clay, which in turn overlies a thick bed of sand that increases in density with depth. Parts of both the upper silty sand and lower sand liquefied and produced hundreds of sand boils. Standard analyses predict that the looser parts of both layers are liquefiable. (Moore-IVI)

ZONE OF TENSILE STRESSES IN THE FOUNDATION OF A CONCRETE DAM (FROM OBSERVATION DATA),
V. N. Durcheva.
Hydrotechnical Construction, Vol. 16, No. 9, p 487-492, September, 1982. 2 Fig, 6 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 9, p 32-35, September, 1982.

Descriptors: *Concrete dams, *Dam foundations, *Tensile strength, Gravity dams, Dam construction, Buttress dams, Seepage, Drainage, *USSR.

The occurrence of a zone of tension under the upstream face from operating loads is possible mainly in high gravity dams of a compressed profile constructed on a rigid foundation. Predicted decompression was confirmed by observation data for the Bratsk and Ust'-Ilim dams. The actual boundaries of the zone of decompression differ from those calculated, due to the effects of numerous technological factors during construction of the dams, which created additional compression or tension in the contact zone. One cause of the increase in the actual zone of decompression, compared to the calculated values, in the sections of the Bratsk dam was the incomplete solidity of the profile when filling of the reservoir began. At the Ust'-Ilim dam, maximum boundaries of decompression higher than those calculated were recorded in the powerhouse sections that absorbed the rise of the upper pool level of an offset profile. In buttress dams, according to the calculations, a zone of decompression should occur. Disturbance of the continuity in the contact plane was not recorded at the Andizhan dam at the normal pool level; at the Kirovskoe dam, under incomplete hydrostatic load, opening of the contact joint occurred, as a consequence of disturbance of the solidity of the contact concrete due to cracking. Compression of the upstream face and contact plane in dams sectioned into columns or elements can reduce the zone of biaxial tension. A reduction in the seepage pressure may lessen the unfavorable consequences of a decompressed foundation. In poorly permeable rocks, draining the foundation can considerably reduce uplift. (Moore-IVI)

A CELL TO STUDY CORROSION OF MATERIALS IN THE WATER SUPPLY INDUSTRY,
Surrey Univ., Guildford (England). Dept. of Metallurgy and Materials Technology.
R. Walker, and R. J. Oliphant.
Journal of the Institution of Water Engineers and Scientists, Vol. 37, No. 2, p 143-150, April, 1983. 5 Fig, 2 Tab, 6 Ref.

Descriptors: *Corrosion, *Water conveyance, Galvanic cell, Solder, Lead, Tin, Copper, Pipes, Contamination, Corrosion control, Hydrogen ion concentration.

A galvanic cell was developed to study the corrosion that occurs when two metals or alloys are joined together and immersed in an electrolyte. The current that flows through the external circuit is used to calculate the rate or intensity of corrosion in static or flowing solutions. Data obtained in a study of solder show that the galvanic corrosion current for lead connected to a copper cathode is much higher than when tin is used. The value for a lead-tin solder anode is intermediate. The effect of the pH of the solution can also be determined and results show that for solder the galvanic current decreases as pH increases. Polarization diagrams can be used to indicate the maximum corrosion current density. Thus, the use of corrosion inhibitors to affect the rate controlling step can then be investigated with this cell. Sodium sulfate appears to act as an anodic corrosion inhibitor because it

affects the anodic curves and decreases the corrosion current from about 15 to 2 microA. The cell is useful in predicting the corrosion that may arise with different combinations of metals and alloys as well as various water conditions. (McKeon-IVI)

RECENT INVESTIGATIONS OF THE EPOXY RESIN LINING OF WATER MAINS,
WRC Engineering, Swindon (England).
R. W. Parkinson, I. C. Warren, and K. J. North.
Journal of the Institution of Water Engineers and Scientists, Vol. 37, No. 3, p 257-271, June, 1983. 7 Fig, 4 Tab, 16 Ref.

Descriptors: *Epoxy resins, *Water mains, *Linings, Microorganisms, Water conveyance.

The transition from laboratory-based trials to full-scale field applications of epoxy resin linings has highlighted problems with the consistent achievement of smooth, pinhole-free linings and the enhancement of non-pathogenic microbial activity in supply. Advancements in both equipment and materials have improved the quality of linings. However, further progress is required consistently to achieve the recommended 1 mm lining thickness. Changes to the epoxy resin formulations have resulted in materials which perform exceptionally well in the National Water Council (NWC) Approvals Scheme. The effect of these changes in supply has not resulted in the eradication of microbial activity, but a reduction in its duration. Recent investigations suggest that the increases are caused by system disruption during renovation and not the lining materials themselves. Work is in progress to assess the durability of these materials and to develop a comprehensive operational guideline manual which will provide the necessary information for the successful implementation of renovation programs using the epoxy resin lining process. Testing the Potential of Aquatic Plants to Treat Abattoir Effluent,
W84-01266 5D

ROTAVIRUSES
Concentration of Simian Rotavirus SA-11 from Tap Water by Membrane Filtration and Organic Flocculation,
W84-01052 5F

ROTIFERS
Response of Planktonic Rotifers to the Eutrophication Process and to the Autumnal Shift of Blooms in Lake Biwa, Japan. I. Changes in Abundance and Composition of Rotifers,
W84-01373 2H

Response of Planktonic Rotifers to the Eutrophication Process and to the Autumnal Shift of Blooms in Lake Biwa, Japan. II. Changes in Fecundity and Turnover Time of the Dominant Species,
W84-01374 2H

ROUTE OF POLLUTANTS
Simulation of Solute Transport in a Chemically Reactive Heterogeneous System: Model Development and Application,
W84-01340 5B

ROUTING
On the Mathematics of Storage Routing,
W84-01217 2E

RUNOFF RATES
Computer Modelling of Snowmelt Flood Runoff in North-East England,
W84-01251 2E

SALINE-FRESHWATER INTERFACES
Harmonizing Ghyben-Herzberg Interface with Rigorous Solutions,
W84-01121 4B

SALINE SOILS
Evaluation of the Hydrodynamic Dispersion Coefficient Using Leached Fraction Equations,
W84-01232 2G

SALINE WATER
Saline Water Use Prospects: Colorado River,
W84-01152 3C

Economics of Irrigation Water Mixing Within a Farm Framework,
W84-01360 3C

SALINE WATER INTRUSION
Salt-Water Intrusion in the Nile Delta,
W84-01120 4B

Harmonizing Ghyben-Herzberg Interface with Rigorous Solutions,
W84-01121 4B

SALINITY
Salt Transport by the South Platte River in Northeast Colorado,
W84-01289 2E

Effects of Large Freshwater Diversions on Benthos of a Mediterranean Lagoon,
W84-01377 5C

SALT MARSHES
Survival of Natural Sewage Populations of Enteric Bacteria in Diffusion and Batch Chambers in the Marine Environment,
W84-01056 5C

Influence of Water Motion on the Distribution and Transport of Materials in a Salt Marsh Estuary,
W84-01243 2L

Growth Response and Spectral Characteristics of a Short Spartina alterniflora Salt Marsh Irrigated with Freshwater and Sewage Effluent,
W84-01299 2L

Tidal Exchange of Nitrogen and Phosphorus Between a Mesohaline Vegetated Marsh and the Surrounding Estuary in the Lower Chesapeake Bay,
W84-01386 2L

The Transport of Bacteria in the Sediments of a Temperate Marsh,
W84-01395 2L

SALTS
Chemical Composition of Rainwater and Floodwaters in the Negev Desert, Israel,
W84-01224 2E

SAMPLING
Monitoring for Water Quality: Fixed Stations versus Intensive Surveys,
W84-01242 5G

Approximate Sampling Distribution of the Serial Correlation Coefficient for Small Samples,
W84-01332 2E

SAND
Liquefaction Sites, Imperial Valley, California,
W84-01098 8D

SAND AQUIFERS
Noordbergum Effect and Characterization of Aquitards at the Rio Maior Mining Project,
W84-01117 2F

SATELLITE TECHNOLOGY
Organizational Needs for Hydrological Applications of Satellite Remote Sensing in Developing Countries,
W84-01103 7B

Use of High Horizontal Resolution Satellite Temperature and Moisture Profiles to Initialize a Mesoscale Numerical Weather Prediction Model - A Severe Weather Event Case Study,
W84-01168 7B

Effective Use of Landsat in Hydrologic Models,
W84-01291 7B

Satellite Observations of the Southern Hemisphere Monsoon During Winter MONEX,
W84-01312 2B

SAUDI ARABIA
Multielemental and Hydrochemical Study of Holy Zamzam Water,
W84-01095 2K

SCALING
Carbonate Deposits in Vacuum Pumps of O'Neill Pumping Plant, California,
W84-01059 3C

SCOUR
Analysis Method for Studying Sedimentation Patterns,
W84-01061 2J

Clear-Water Scour at Cylindrical Piers,
W84-01138 8B

Confluence Scour in Coarse Braided Streams,
W84-01330 2J

SEA GRASSES
Distribution of Some Metallic Elements in Eelgrass (Zostera marina L.) and Sediment in the Limfjord, Denmark,
W84-01393 2L

SEASONAL DISTRIBUTION
Daily Precipitation Occurrences Modelling with Markov Chain of Seasonal Order,
W84-01099 2B

Associations Between Anomalies of Temperature and Precipitation in the United States and Western Northern Hemisphere 700 mb Height Profiles,
W84-01174 2B

SEAWATER
Studies on the Anodic Stripping Voltammetry of Lead in Polluted Estuarine Waters,
W84-01060 5A

SEDGE
Productivity, Detritus Flux, and Nutrient Cycling in a Carex lyngbyei Tidal Marsh,
W84-01380 2L

SEDIMENT DISTRIBUTION
Analysis Method for Studying Sedimentation Patterns,
W84-01061 2J

SEDIMENT SUSPENSION
Sediment Suspension with Rippled Bed,
W84-01131 8B

SEDIMENT TRANSPORT
Determination of the Cross Section of Canal Channels for Sediment Transport,
W84-01068 8B

Steady Bed Material Transport in Alluvial Channels,
W84-01136 2J

Nonequilibrium Bedload Transport by Steady Flows,
W84-01137 2J

Semi-Empirical Correlations for Fine and Coarse Cohesionless Sediment Transport,
W84-01248 2J

Densities of Wet Aggregated Sediment from Different Textured Soils,
W84-01366 2J

SEDIMENTATION BASINS
Dredged Material Sedimentation Basin
W84-01109

SEDIMENTS
Effects of Organic Matter Additions to S
on the Growth of Aquatic Plants,
W84-01183

A Sensitive Method for Measuring
Carbon in Sediment,
W84-01272

Sulphur in Sediments Chronicles Past
in Lake Acidification,
W84-01301

Evaluation of Extraction Techniques for
termination of Heavy Metals in River Sed
W84-01375

SEEPAGE
Probabilistic Updating of Pore Pressure
W84-01080

SEPARATION TECHNIQUES
Oil Removal from Water in Parallel Plat
ity-Type Separators,
W84-01264

SETTLING BASINS
Protective Ponds Save Ecorse Creek,
W84-01325

SEWER INFILTRATION
Manhole Inflow and Infiltration Stoppe
Special Repairs,
W84-01318

SEWER SYSTEMS
Protective Ponds Save Ecorse Creek,
W84-01325

SHALLOW FLOW
Steady Shallow Flow Over Curved Beds,
W84-01240

SHEAR
Centrifugal Modeling of Soil Liquefactio
ceptibility,
W84-01081

SHOALING PROCESSES
Shoaling Processes in Navigable Waters,
W84-01130

SHOALS
Analysis Method for Studying Sedimen
Patterns,
W84-01061

Shoaling Processes in Navigable Waters,
W84-01130

SHRIMP
Oxygen Consumption in the Shrimp, Palae
etes pugio, Exposed to Fluctuating Tem
tures and Food Contaminated with the Dia
tic Petroleum Hydrocarbon, Dimethylnap
lene,
W84-01390

SILICA
Lessons from the Silica 'Decline' in Lake M
gan,
W84-01083

SILICON
Silicon Consumption and Population Dy
Changes of Dominant Planktonic Diatom
Lake Constance,
W84-01181

SILT LOAD
Settling Quiets the Storm Effects,
W84-01317

ING
termination of the Cross Section of Canal annels for Sediment Transport,
4-01068 8B

SELECTION
eather Station Siting and Consumptive Use imates,
4-01144 2B

nnesota's Hazardous Waste Siting Criteria,
4-01146 5G

GE
ption and Release of Cadmium by Some vage Sludges,
4-01192 5E

GE CONDITIONING
re to Learn about Disinfection,
4-01324 5D

dge Disinfected with Electron Beams,
4-01326 5E

GE DISPOSAL
tures of Federal Law That Encourage Adop- of Land Application of Wastewater,
4-01143 5G

racteristics of Combined Effluent Treatment lges from Several Types of Pulp and Paper s,
4-01186 5E

avior of Chromium in Soils: V. Fate of Or- cally Complexed Cr(III) Added to Soil,
4-01201 5E

GE DRYING
ificance of ATP in the Settlement of Acti- d Sludge,
4-01167 5E

L WATERSHEDS
d Frequency Analysis for Small Watersheds outhern Illinois,
4-01276 2E

onal Variations of Cd, Pb, Cu and Ni Levels now from the Eastern Arctic Ocean,
4-01308 5B

ipitation Chemistry at the Marcell Experi- al Forest in North Central Minnesota,
4-01345 2K

COVER
v Cover and Temperature Relationships in h America and Eurasia,
4-01170 2C

Influence of Snow on Growth and Survival anted Trees,
4-01382 2I

MELT
tion-Triggered Avalanche, Flood, and r at Mount St. Helens - Effects of Winter vpack,
01082 2C

al Floods in Southwestern British Colum- Canada,
01229 2E

puter Modelling of Snowmelt Flood Runoff rth-East England,
01251 2E

GGREGATES
Water Matric Potential Effects on Aggre- Stability,
01161 2J

ties of Wet Aggregated Sediment from rent Textured Soils,
01366 2J

SOIL COMPACTION
Optimum Moisture Content for Compacting Soils: One-Point Method,
W84-01151 2G

SOIL CONTAMINATION
Microbial Treatment of Soil to Remove Pentachlorophenol,
W84-01091 5G

SOIL CRUSTS
Modeling Infiltration into Crusted Soils by the Green-Ampt Approach,
W84-01254 2G

SOIL DENSITY
Densities of Wet Aggregated Sediment from Different Textured Soils,
W84-01366 2J

SOIL DISPOSAL FIELDS
Ground-Water Mounding Due to On-Site Sewage Disposal,
W84-01154 5G

SOIL LIQUEFACTION
Centrifugal Modeling of Soil Liquefaction Susceptibility,
W84-01081 8D

SOIL MANAGEMENT
Proxy Variables from Pollution Control,
W84-01198 4C

Soil Management as it Affects Nutrient Losses from a Tropical Soil in Nigeria,
W84-01209 5G

SOIL SATURATION
Aquic Moisture Regimes in Soils with and without Low Chroma Colors,
W84-01298 2G

SOIL SUFFOSION
Movement of Fine Grains in the Vicinity of Well Screens,
W84-01101 8B

SOIL SURFACES
Modeling Infiltration into Crusted Soils by the Green-Ampt Approach,
W84-01254 2G

Simple Measurements of Soil Surface Microrelief Characteristics,
W84-01282 2G

SOIL TEMPERATURE
Experimental Verification of a Model to Predict Soil Moisture and Temperature Profiles,
W84-01255 2G

SOIL VOLUME
General Soil Volume Change Equation: I. The Two-Parameter Model,
W84-01399 2G

SOIL WATER
Drought Analysis and Soil Moisture Prediction,
W84-01149 3F

Soil Water Matric Potential Effects on Aggregate Stability,
W84-01161 2J

Assessment of Evaporation from Bare Soil by Infrared Thermometry,
W84-01162 2G

Vertical Infiltration of Water into Unsaturated Soils with Variable Diffusivity and Conductivity,
W84-01219 2G

Soil-Water Residence Time and Solute Uptake; 2. Dye Tracing and Preferential Flow Predictions,
W84-01220 2G

Surface Soil Moisture Variation on Small Agricultural Watersheds,
W84-01225 2G

Experimental Verification of a Model to Predict Soil Moisture and Temperature Profiles,
W84-01255 2G

Influence of Velocity on Hydrodynamic Dispersion During Unsteady Soil Water Flow,
W84-01256 2G

Leaching Characteristics of a Stony Desert Soil,
W84-01257 2G

Simulating Soil Water Recession Coefficients for Agricultural Watersheds,
W84-01280 2E

Aquic Moisture Regimes in Soils with and without Low Chroma Colors,
W84-01298 2G

A Soil and Atmospheric Boundary Layer Model for Evapotranspiration and Soil Moisture Studies,
W84-01339 2G

Estimating Profile Water Storage from Surface Zone Soil Moisture Measurements under Bare Field Conditions,
W84-01341 2G

Unsaturated Flow in Spatially Variable Fields; 1. Derivation of Models of Infiltration and Redistribution,
W84-01342 2G

Unsaturated Flow in Spatially Variable Fields; 2. Application of Water Flow Models to Various Fields,
W84-01343 2G

General Soil Volume Change Equation: I. The Two-Parameter Model,
W84-01399 2G

SOIL-WATER-PLANT RELATIONSHIPS
Stream Flow in Relation to Ohia Forest Decline on the Island of Hawaii,
W84-01284 2E

SOLUBILITY
Further Water Solubility Determinations of Insecticidal Compounds,
W84-01176 5B

Behavior of Chromium in Soils: V. Fate of Organically Complexed Cr(III) Added to Soil,
W84-01201 5E

Behavior of Chromium in Soils. VI. Interactions Between Oxidation-Reduction and Organic Complexation,
W84-01202 2G

SOLUTE TRANSPORT
Simulation of Solute Transport in a Chemically Reactive Heterogeneous System: Model Development and Application,
W84-01340 5B

Combined Mixing Cell/Analytical Model to Describe Two-Dimensional Reactive Solute Transport for Unidirectional Groundwater Flow,
W84-01351 5B

Unsaturated Flow in Spatially Variable Fields; 3. Solute Transport Models and Their Application to Two Fields,
W84-01364 2G

SORPTION
Sorption of Polychlorinated Biphenyls (PCB) To Clay Particulates and Effects of Desorption on Phytoplankton,
W84-01262 5C

SOUTH PLATTE RIVER
Salt Transport by the South Platte River in Northeast Colorado,
W84-01289 2E

SPARTINA
Growth Response and Spectral Characteristics of a Short Spartina alterniflora Salt Marsh Irrigated with Freshwater and Sewage Effluent,
W84-01299 2L

SPECIATION
Neptunium and Americium Speciation in Selected Basalt, Granite, Shale, and Tuff Ground Waters,
W84-01086 5B

SPECIFIC CONDUCTIVITY
The Chemical Composition of Lakes in the North-Central United States,
W84-01246 2H

SPILLWAYS
Uniform Region of Self-Aerated Flow,
W84-01133 8B

SPRINKLER IRRIGATION
Statistical Analysis of Line-Source Sprinkler Experiments and Other Nonrandomized Experiments Using Multivariate Methods,
W84-01187 3F

STAGE-DISCHARGE RELATIONS
Flood Routing on a Small Computer,
W84-01089 7C

STATIONARY WAVES
Waves in Meandering Streams,
W84-01239 8B

STATISTICAL ANALYSIS
Statistical Analysis of Line-Source Sprinkler Experiments and Other Nonrandomized Experiments Using Multivariate Methods,
W84-01187 3F

Velocity Equation for Water Quality Modeling in Georgia,
W84-01277 5A

STATISTICAL METHODS
An Investigation of the Cellular Structure of Storms Using Correlation Techniques,
W84-01367 2B

STATISTICAL MODELS
On the Analysis of Extreme Rainfalls,
W84-01228 2B

Spatial-Temporal Model of Storm Rainfall,
W84-01231 2B

One-Dimensional Stochastic Model of Ice Motion in Western Norton Sound, Alaska, U.S.A.,
W84-01381 2C

STOCHASTIC PROCESS
Incorporating the Stochastic Nature of Water Quality into Management,
W84-01397 5G

STORAGE
On the Mathematics of Storage Routing,
W84-01217 2E

STORM RUNOFF
Mechanism of Runoff Generation from an Alpine Glacier During a Storm Traced by Oxygen O18/O16,
W84-01221 2E

STORM SEEPAGE
Water and Nitrate-Nitrogen Losses From a Small, Upland, Coastal Plain Watershed,
W84-01188 2A

STORM WATER
Stormwater Quality Characteristics in Detention Basins,
W84-01108 5G

Settling Quiets the Storm Effects,
W84-01317 8B

STORMS
Changes in the Nature of Fluctuations of Temperature and Liquid Water Content During the Lifetime of a Large-Scale Storm,
W84-01173 2B

STREAM BEDS
Bar Resistance in Gravel Bed Streams at Bankfull Stage,
W84-01347 2E

STREAM DISCHARGE
Stream Flow in Relation to Ohia Forest Decline on the Island of Hawaii,
W84-01284 2E

Salt Transport by the South Platte River in Northeast Colorado,
W84-01289 2E

Technique to Reconstruct River Discharge History from Tree-Rings,
W84-01290 2E

STREAMFLOW
Approximate Sampling Distribution of the Serial Correlation Coefficient for Small Samples,
W84-01332 2E

A Simplified Semiempirical Approach to Probabilities of Extreme Hydrologic Droughts,
W84-01344 2B

Evaluations of Water Balance Models on a Mixed Conifer Watershed,
W84-01349 2A

Evaluations of Water Balance Models on a Mixed Conifer Watershed,
W84-01350 2A

SUBMERGED PLANTS
Chesapeake Bay: An Unprecedented Decline in Submerged Aquatic Vegetation,
W84-01329 2L

Distribution of Some Metallic Elements in Eelgrass (Zostera marina L.) and Sediment in the Limfjord, Denmark,
W84-01393 2L

SUBSTRATES
Influence of Substratum Wettability on Attachment of Freshwater Bacteria to Solid Surfaces,
W84-01053 5D

SUCCESSION
Spring Bloom in a Hypereutrophic Lake, Lake Kasumigaura, Japan-II; Succession of Phytoplankton Species,
W84-01269 2H

SULFUR
The Regional Effects of the Effluents from the Mishraq Sulphur Mines in Iraq on the Hydrological System,
W84-01105 5B

Effect of Liming and Leaching on the Sulfur-Supplying Capacity of Soils,
W84-01258 5B

Sulphur in Sediments Chronicles Past Changes in Lake Acidification,
W84-01301 5B

SULFUR COMPOUNDS
Sensitivity Analysis of the Kinetics of Acid Rain Models,
W84-01128 5A

SURFACE FLOW
Coupled Surface Water and Groundw
Catchment Model,
W84-01398

SURFACE RUNOFF
Water and Nitrate-Nitrogen Losses Fro
Small, Upland, Coastal Plain Watershed,
W84-01188

Simple Measurements of Soil Surface Mic
lief Characteristics,
W84-01282

SURVEYS
An Application of Operations Research M
ods to Beach Renourishment Projects,
W84-01279

SUSPENDED SEDIMENTS
Suspended Sediment Profile for Ice-Cov
Flows,
W84-01135

Evaluation of a Depth Proportional In
Device for Automatic Pumping Samplers,
W84-01274

Contamination of Successive Samples in Po
ble Pumping Systems,
W84-01363

Behaviour of Copper, Zinc, Iron and Manga
during Experimental Resuspension and Reox
tion of Polluted Anoxic Sediments,
W84-01396

SUSPENDED SOLIDS
The Effect of Suspended Solids in Wastew
on Soil Hydraulic Conductivity: I. Suspen
Solids Labelling Method,
W84-01252

The Effect of Suspended Solids in Wastew
on Soil Hydraulic Conductivity: II. Verti
Distribution of Suspended Solids,

Adsorption of Lead on the Suspended Partic
of River Water,
W84-01273

TANNERY WASTES
Behavior of Chromium in Soils. VI. Interactio
Between Oxidation-Reduction and Orga
Complexation,
W84-01202

TASTE
Ensuring Water Quality in a Distributi
System,
W84-01124

TEMPERATURE EFFECTS
Effect of Temperature on the Growth of Micr
bial Film in a Model Trickling Filter,
W84-01263

The Influence of Spring and Fall Temperatur
on the Avoidance Response of Juvenile Atlan
Menhaden, Brevoortia tyrannus, Exposed to S
multaneous Chlorine-delta T Conditions,
W84-01275

TENSILE STRENGTH
Zone of Tensile Stresses in the Foundation of
Concrete Dam (from Observation Data),
W84-01067

TETRACHLOROETHYLENE
Tetrachloroethylene (TCE) Concentration R
duction in Vinyl-Lined Asbestos Cement Wat
Mains Through the Application of Cemen
Mortar Linings,
W84-01155

TEXAS
Basin Recharge of Playa Water,
W84-01148

ERMAL INJECTION
emperature Distribution Around a Well uring Thermal Injection and a Graphical echnique for Evaluating Aquifer Thermal operties,
84-01362 6G

RMAL POLLUTION
ccurrence and Pathogenicity of Naegleria owleri in Artificially Heated Waters,
84-01055 5C

ffects of Temperature and Color Components Wastewater Discharges on Aquatic Commu-ies,
84-01164 5C

oling Water Discharges into a Sea with a ping Bed,
84-01261 2L

OUGHFALL
sponse of Spruce and Birch Foliage to Leach- by Acidic Mists,
84-01200 5B

AL CURRENTS
dal and Low-frequency Net Displacement in a astal Lagoon,
84-01378 2L

rculation Changes in the Sheepscot River Es-ry, Maine, Following Removal of a Cause-y,
84-01379 2L

AL EFFECTS
oling Water Discharges into a Sea with a ping Bed,
84-01261 2L

dal and Subtidal Water Volume Exchange in Estuarine System,
84-01383 2L

rtical Mixing at the Head of the Laurentian annel,
84-01387 2L

AL EXCHANGE
al Exchange of Nitrogen and Phosphorus ween a Mesohaline Vegetated Marsh and the rrounding Estuary in the Lower Chesapeake y,
84-01386 2L

AGE PRACTICES
l Management as it Affects Nutrient Losses n a Tropical Soil in Nigeria,
84-01209 5G

OGRAPHY
mple Measurements of Soil Surface Microre-Characteristics,
84-01282 2G

ects of Land Use and Topography on Some ter Quality Variables in Forested East Texas,
84-01288 5G

CITY
xic Effects of Two Organophosphorus Pesti-es on Fructose-1,6-Diphosphate Aldolase Ac-ty of Liver, Brain and Gills of the Fresh-er Fish Clarias batrachus,
84-01113 5C

siological Changes in Carps Induced by Pol-on,
84-01129 5C

ects of Temephos on the Respiratory Rate of Salt Marsh Amphipod, Gammarus mucrona-

84-01296 5C

ygen Consumption in the Shrimp, Palaemon-pugio, Exposed to Fluctuating Tempera-tures and Food Contaminated with the Diaromatic Petroleum Hydrocarbon, Dimethylnaphthalene,
W84-01390 5C

TREES
The Influence of Snow on Growth and Survival of Planted Trees,
W84-01382 2I

TRICKLING FILTERS
Effect of Temperature on the Growth of Microbial Film in a Model Trickling Filter,
W84-01263 5D

The Trickling Filter Finds a New Partner,
W84-01328 5D

TRITIUM
Isotopic Investigation of a Near-Surface Groundwater System,
W84-01102 2G

TUNNEL CONSTRUCTION
Calculation of Linings of a System of Parallel Round Tunnels,
W84-01071 8A

TUNNEL LININGS
Calculation of Linings of a System of Parallel Round Tunnels,
W84-01071 8A

TURBIDITY
Clear Water for Cayuga,
W84-01322 5F

TURBULENT FLOW
Sediment Suspension with Rippled Bed,
W84-01131 8B

Flow Near Groin-Like Structures,
W84-01134 8B

TURBULENT FLOWS
Suspended Sediment Profile for Ice-Covered Flows,
W84-01135 2J

TURKEY
Application of Network Design Procedures For Redesigning Kizilirmak River Basin Raingauge Network, Turkey,
W84-01100 7A

ULTRAVIOLET RADIATION
Bioassay and Dose Measurement in UV Disinfection,
W84-01051 5D

Mineralization of Organic Matter in Water by U.V. Radiation,
W84-01265 5A

UNIFORMITY COEFFICIENT
Interrelationships of Irrigation Uniformity Terms,
W84-01147 3F

UNSATURATED FLOW
Unsaturated Flow in Spatially Variable Fields; 3. Solute Transport Models and Their Application to Two Fields,
W84-01364 2G

UNSTEADY FLOW
Difference Methods of Flow in Branch Channel,
W84-01132 8B

Influence of Velocity on Hydrodynamic Dispersion During Unsteady Soil Water Flow,
W84-01256 2G

UPFLOW SLUDGE BLANKET
Anaerobic Treatment of Dilute Wastewaters Using an Upflow Sludge Blanket Reactor,
W84-01114 5D

UPLIFT PRESSURE
Consideration of the Uplift Pressure of Water in Calculations of the Stability of Concrete Dams on Rock Foundations,
W84-01069 8A

URBAN AREAS
Effects of Population and Industrial Change on Environmental Quality in Major Conurbations,
W84-01207 5G

USSR
Zone of Tensile Stresses in the Foundation of a Concrete Dam (from Observation Data),
W84-01067 8F

Determination of the Cross Section of Canal Channels for Sediment Transport,
W84-01068 8B

UTILITIES
Water Utility Compliance with Hazardous Materials, Substances and Waste Regulations,
W84-01159 5G

A Unique Opportunity to Upgrade Water/Wastewater Systems,
W84-01336 5D

VEGETATION
Effects of Bioclimate and Soil Use on Water Budget Terms in West Africa (Influence du Bioclimat et de l'Amenagement des Sols sur les Elements du Bilan Hydrique en Afrique de l'Ouest),
W84-01104 2A

VIBRATIONS
Vibration of Hydraulic Gates,
W84-01074 8C

VIRUSES
Confirmed Viruses Versus Unconfirmed Plaques in Sewage,
W84-01125 5D

VISCOSITY
Secondary Flows and Their Significance in the Design and Operation of Hydraulic Structures,
W84-01077 8B

VOLCANOES
Mount St. Helens Eruptive Impacts to the Toutle Community Ground-Water Supply,
W84-01058 5F

Eruption-Triggered Avalanche, Flood, and Lahar at Mount St. Helens - Effects of Winter Snowpack,
W84-01082 2C

VOLTAMMETRY
Studies on the Anodic Stripping Voltammetry of Lead in Polluted Estuarine Waters,
W84-01060 5A

WASTE DISPOSAL
Neptunium and Americium Speciation in Selected Basalt, Granite, Shale, and Tuff Ground Waters,
W84-01086 5B

Minnesota's Hazardous Waste Siting Criteria,
W84-01146 5G

Mercury, A Hazardous Waste Problem,
W84-01206 5D

WASTEWATER
Confirmed Viruses Versus Unconfirmed Plaques in Sewage,
W84-01125 5D

WASTEWATER ANALYSIS
Confirmed Viruses Versus Unconfirmed Plaques in Sewage,
W84-01125 5D

WASTEWATER DISPOSAL
Features of Federal Law That Encourage Adoption of Land Application of Wastewater,
W84-01143 5G

Ground-Water Mounding Due to On-Site Sewage Disposal,
W84-01154 5G

Behavior of Chromium in Soils: V. Fate of Organically Complexed Cr(III) Added to Soil,
W84-01201 5E

The Effect of Suspended Solids in Wastewater on Soil Hydraulic Conductivity: II. Vertical Distribution of Suspended Solids,
W84-01253 5D

WASTEWATER FACILITIES
Going Deep Cuts Sewer, Lift Station Costs,
W84-01316 5F

A Unique Opportunity to Upgrade Water/Wastewater Systems,
W84-01336 5D

WASTEWATER IRRIGATION
Alfalfa, Sweetcorn, and Wheat Responses to Long-Term Application of Municipal Waste Water to Cropland,
W84-01194 5D

The Effect of Suspended Solids in Wastewater on Soil Hydraulic Conductivity: II. Vertical Distribution of Suspended Solids,
W84-01253 5D

WASTEWATER MANAGEMENT
Requirements for Wastewater Handling Systems: Second-Round Update,
W84-01235 6E

WASTEWATER POLLUTION
Ground-Water Transport from Wastewater Infiltration,
W84-01110 5B

WASTEWATER TREATMENT
Bioassay and Dose Measurement in UV Disinfection,
W84-01051 5D

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 17, NUMBER 5
MAY 1984

DEPOSITORY

APR 20 1984

UNIVERSITY OF ILLINOIS
AT URBANA-CHAMPAIGN

1 -- W84-01769
SWRABW

DOCUMENT OF U.S. URBAN-PLANNER

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 5
MAY 1984

W84-01401 -- W84-01769

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

ANNUAL PATTERN AND SPATIAL DIS- UTION OF AQUATIC OXYGEN METAB- M IN BOREAL FOREST WATERSHEDS,
s Hole Oceanographic Institution, MA.
Saiman.
gical Monographs, Vol. 53, No. 1, p 73-94, 3 Fig, 10 Tab, 40 Ref.

ptors: *Oxygen metabolism, *Forest water- *Aquatic ecosystems, Periphyton, Mosses, phytes, Organic matter, Primary productiv- etabolism, Streams, rivers, Lakes, Phyto- on, Spatial distribution, Channel morphol- uebec.

vel and diversity of metabolism in lotic ems are largely functions of channel geo- ology and hydrology, making site-specific difficult to extrapolate to other parts of the ed. This paper describes the pattern and ition of aquatic oxygen metabolism for un- ted boreal forest watersheds in eastern , Canada. Metabolism by periphyton, macrophytes, fine particle organic matter M: 0.5 micrometer-1mm), and coarse particu- ganic matter (CPOM: > 1mm) was exam- ring the ice-free period (April to Novem- 1979 and 1980 in First Choice Creek (first 207 sq km), Matemek River (sixth order; 673 and the Moisie River (ninth order; 19,871 As watershed area increases, primary pro- and the number of autotrophic groups are ted with moss and macrophyte communi- otal O2 metabolism increases downstream, from < 1 g/sq m/d in First Choice Creek ly 5 g/sq m/d during summer in the Moisie utotrophic metabolism is not normally cor- with light or chlorophyll, but annual O2 tion is highly correlated with stream order .76 in most cases). These data are com- with a geomorphological analysis of the ed to discern the spatial distribution of metabolism, and to estimate total aquatic ism in the Moisie River drainage network. occurring only in streams of fourth or order, are the most productive autotrophic ent in the watershed (3.9 x 10 to the 10th g/yr); by comparison, periphyton produce x 10 to the 10th power g/yr. FPOM is the most active detrital component (6.6 x 10 to the 10th power g/yr). Geomorphic analyses show that streams of fourth or higher order compromise only 1.2% of the total number and 12.7% of the total length, but have 76.8% of the lotic surface area, and are responsible for 86.3% of the gross production by the entire lotic drainage network. The surface area of lakes is approximately six times that of streams, but their contribution (phytoplankton) to total aquatic ecosystems metabolism is comparable only to that of lotic periphyton. Results demonstrate that the River Continuum Concept can be extended to the watershed level by combining biological measurements with geomorphological analyses of the drainage network, thus allowing a detailed description of spatial and temporal patterns for specific metabolic components and total ecosystem metabolism to be constructed. AN EPHEMERAL STREAM-AQUIFER INTERACTION MODEL,
Adelaide Univ. (Australia). Dept. of Civil Engineering.
P. J. Dillon, and J. A. Liggett.
Water Resources Research. Vol. 19. No. 3 p 621-626, June, 1983. 13 Fig, 13 Ref. NSF grant CEE-7902803.

Descriptors: *Ephemeral streams, *Aquifers, *Hydraulic models, Streambeds, Groundwater movement, Water level fluctuations, Mathematical models, Green-Ampt equation, Boundary conditions, Boundary integral equation, Stream discharge, Australia, Little Para River.

The boundary integral equation method is applied to the interaction between an ephemeral stream and an unconfined aquifer through a semipervious streambed. The resulting two-dimensional vertical slice model describes groundwater flow when the stream and aquifer are hydraulically disconnected or connected as well as the transition between these two states. It incorporates the Green-Ampt equation with the hydraulically disconnected boundary conditions. The model was successfully calibrated using stream discharge and bore hydrograph data from the Little Para River recharge study, South Australia. It predicts with sufficient accuracy the inflow and outflow from the stream to the aquifer during fluctuating water levels in the stream. (Author's abstract)

HIMALAYAN WINTER SNOW COVER AREA AND SUMMER MONSOON RAINFALL OVER INDIA,
Howard Univ., Washington, DC. Dept. of Geology and Geography.
B. Dey, and O. S. R. U. Bhandu Kumar.
Journal of Geophysical Research, Vol. 88, No. C9, p 5471-5474, June 20, 1983. 3 Fig, 2 Tab, 22 Ref.

Descriptors: *Snow cover, *Monsoons, *Rainfall, Satellite imagery, Correlation analysis, Himalayas, India.

The study presented in this paper examines the relationship between satellite-derived Himalayan snow cover extent in the winter season (December to March) and the amount of summer monsoon rainfall for the period 1971 to 1980. Himalayan snow cover area has been derived from satellite images and northern hemisphere snow cover charts produced by the National Oceanic and Atmospheric Administration National Environmental Satellite Service. Indian summer monsoon rainfall was the area-weighted mean of all meteorological subdivisions of India for the months June through September. The variations of Indian summer monsoon rainfall were compared with the variation of the Himalayan winter snow cover area. There is an inverse relationship (negative correlation) between these two variables, which indicated that more than mean Himalayan winter snow cover area is to be followed by less than normal (India Meteorological Department (IMD)) summer monsoon rainfall over India. The inverse relationships hold true for 8 out of 10 years of the study period. The coefficients of the correlation between the Himalayan snow cover area departures from the 10-year mean and the rainfall departures from IMD normals for all the meteorological subdivisions of India were computed. The negative correlations were found to be maximum in the region between 18 degrees N latitude and the foothills of the Himalayas. (Author's abstract)

2C. Snow, Ice, and Frost

ICE BREAKUP AND JAMMING OBSERVATIONS ALONG THE MACKENZIE RIVER,
Queen's Univ., Kingston (Ontario). Dept. of Civil Engineering.
J. W. Kamphuis, and J. R. Moir.
Canadian Journal of Civil Engineering, Vol. 10, No. 1, p. 78-91, March, 1983. 14 Fig, 1 Tab, 2 Ref.

Descriptors: *Ice breakup, Ice jams, Melting, Mackenzie River, Canada.

The breakup of ice along the Mackenzie River between Fort Simpson and Fort Good Hope was studied in 1979, 1980, 1981, and 1982. This paper describes the 1980 and 1981 observations. An aircraft dedicated to this task was used to make over 40 observation flights during those two breakup seasons in which more than 20 major ice jams were observed during their formation, stationary position, and breakup. Although the paper is based on experience gained during only 4 years, it was found that all observed jams displayed the same major characteristics; hence it appears that general descriptions of ice melting, breakup, and jamming for the section of the Mackenzie River under investigation are possible. Although there could be additional variations, these are expected to be minor. The paper describes the ice melting process prior to any ice movement. The ice jamming process as it takes place along the Mackenzie River is discussed as well as the various parameters that affect this process. Several secondary factors that influence the detailed character of the jams are also addressed. (Author's abstract)

2D. Evaporation and Transpiration

ESTIMATION OF STREAMFLOW LOSS BY EVAPOTRANSPIRATION FROM A RIPARIAN ZONE,
Vrije Univ., Amsterdam (Netherlands). Inst. of Earth Sciences.
E. Seyhan, A. S. Hope, and R. E. Schulze.
South African Journal of Science, Vol. 19, No. 3, p 88-90, March, 1983. 2 Fig, 3 Tab, 10 Ref.

Descriptors: *Riparian water loss, *Evapotranspiration, Streamflow, Factor analysis, Correlation analysis, Regression analysis, Diurnal variation, Recession hydrograph, South Africa.

Recession hydrographs from a small research catchment in Zululand (South Africa) exhibited diurnal fluctuations in streamflow which were superimposed on the general recession trend. The daily additional reduction in flow was assumed to be the result of greater evapotranspirational losses in the riparian zone during the day. This reduction in flow was calculated for 76 days and an attempt was made to relate these values to hydrometeorological variables which could be expected to correlate with evapotranspirational losses. Factor analysis, correlation analysis and regression analysis were used to develop equations to estimate the daily additional reduction in streamflow. These equations were found to be satifactory with hydro-

graph stage being the most important independent variable. (Author's abstract)
W84-01443

EVAPOTRANSPIRATION OF EICHHORNIA CRASSIPES (MART.) SOLMS AND LEMNA MINOR L. IN CENTRAL FLORIDA: RELATION TO CANOPY STRUCTURE AND SEASON,
Florida Univ., Gainesville.
T. A. DeBusk, J. H. Ryther, and L. D. Williams.
Aquatic Botany, Vol. 16, No. 1, p 31-39, May, 1983. 5 Fig, 1 Tab, 12 Ref.

Descriptors: *Water hyacinth, *Evapotranspiration, Canopy, Seasonal variation, Temperature, Solar radiation, Duckweed, Evaporation, Water loss.

A major concern regarding water hyacinth (Eichhornia crassipes) infestations is the increased loss of water through evapotranspiration. However literature estimates of the evapotranspiration to open water evaporation ratio for Eichhornia may vary widely, from 1.4 to 3.7. Evapotranspiration of the freshwater macrophytes E. crassipes and Lemna minor was examined in tank cultures in Ft. Pierce, Florida. L. minor is a plant which grows essentially in two dimensions with little canopy variation. Evapotranspiration of both species during the year 1979 was significantly correlated with open water evaporation, solar radiation and mean temperature. Evapotranspiration of Eichhornia fluctuated by ca. 40% when its canopy structure was varied by manipulating plant stocking density or nutrient availability. Similar variations in canopy structure which commonly occur in natural stands of Eichhornia limit the value of evapotranspiration estimates made over a wide temporal or areal basis. Eichhornia is a floating plant adapted to riverine systems where expansions or reductions in habitat frequently occur, so the species rapidly responds to changing environmental parameters by varying its canopy structure and standing crop. W84-01453

EFFECT OF TRANSIENT, PARTIAL-AREA SHADING ON EVAPORATION FROM A BARE SOIL,
Kyushu Univ., Fukuoka (Japan). Irrigation Engineering Lab.
Y. Nakano, T. Cho, and D. Hillel.
Soil Science, Vol. 135, No. 5, p 282-295, May, 1983. 11 Fig, 11 Ref.

Descriptors: *Evaporation, *Soil surface, *Shade, Mathematical models, Simulation, Canopy, Water transport, Energy, Soil temperature, Soil water.

To evaluate the consumptive use efficiency of irrigated water, it is of interest to estimate the soil surface evaporation component of what is generally described by the term evapotranspiration. Interception of radiation by foliage is one of the major factors influencing evaporation. A three-dimensional mechanistic model describing soil-atmosphere energy exchange and water transport was developed in an effort to account for the effect of time-varying and space-variable shading on evaporation from a bare soil. A simple model of an inert (nontranspiring) plant was used to demonstrate the effect of shading on evaporation from the soil surface. The plant was represented hypothetically as an opaque, nonreflective sphere with the properties of a black-body emitter. During the course of a day, the effect of a canopylike shading body was to create a west-to-east shaded band in which soil surface temperature and evaporation were reduced (in comparison with a continuously sunlit surface) and soil moisture was enhanced. (Moore-IVI)
W84-01600

REPETITIVE-LOAD BEHAVIOR OF UNSATURATED SOILS,
E. S. Motan, and T. B. Edil.
Transportation Research Record, Vol. 872, p 41-48, 1982. 17 Fig, 1 Tab, 17 Ref.

Descriptors: *Soil mechanics, *Soil saturation, *Soil water suction, Sand, Clay, Plasticity, Matrix suction, Soil water, Soil compaction.

The resilient and residual deformation behavior of a number of soil samples under unconfined repetitive loading was investigated in the unsaturated state as a function of matrix suction. Matrix suction values within the range of 50-1500 kPa were achieved by using pressure-plate extractors. Results obtained during the first phase of the study on low-plasticity sand and clay mixtures are extended to high-plasticity clay during the second phase after a series of repetitive-load tests on statically compacted samples of grundite at both dry- and wet-of-optimum compaction moisture content. The resilient modulus is shown to be related to the matrix suction in a rather unique form for all soils tested; the maximum is at 800 kPa suction and it decreases thereafter and subsequently increases again significantly at very high suction values (as in the air-dried or oven-dried state). This maximum resilient modulus obtained at 800-kPa suction increases with decreasing plasticity index. The position and the form of the curve of resilient modulus versus matrix suction may undergo changes if deviator stress and confining pressure are introduced as variables. It is also shown that the resilient behavior of cohesive soils does not follow the same pattern as the relationship of unconfined strength versus suction beyond a suction value of 800 kPa. Furthermore, the postrepetetive testing unconfined strength of dry- and wet-of-optimum compacted samples seems to be better correlated with the moisture content than with the soil suction value. (Author's abstract)
W84-01755

2E. Streamflow and Runoff

FLOW TRANSFORMATIONS IN SEDIMENT GRAVITY FLOWS,
California Univ., Santa Barbara. Dept. of Geological Sciences.
R. V. Fisher.
Geology, Vol. 11, No. 5, p 273-274, May, 1983. 1 Fig, 26 Ref.

*Flow characteristics, *Gravity flow, *Sediment transport, Flow measurement, Streamflow, Runoff, Turbulent flow, Laminar flow.

Sediment gravity flows (subaerial or subaqueous) exhibit flow transformations, defined as changes in flow behavior between laminar and turbulent states. Laminar-turbulent transformations are influenced chiefly by particle concentration, thickness of the flow, and flow velocity (slope). At least four kinds of flow transformations can be identified: body transformations, gravity transformations, surface transformations, and fluidization transformations. Slumps or debris flows may change to turbidity currents with no change in water content when velocity is great enough to produce internal turbulence. The way that particles are supported within a flow in its final stages of movement largely determines the textures and structures within a bed. The manner of support is a direct function of particle concentration and amount of fine-grained cohesive sediment mixed with pore fluid, which in turn greatly affects whether or not laminar to turbulent or turbulent to laminar transformations take place. The concept of flow transformations is qualitatively useful in visualizing flow dynamics leading to the sequential development of beds within single depositional units. (Baker-IVI)

Soil properties have profound effects on ov flows over porous media. These effects are i gated by using a surface-subsurface flow co tive simulation model which solves the Venant equations for the overland flow and ards' equation for the two-dimensional unsat and saturated porous medium flow. Guided dimensional analysis, four soil properties are ied, namely, porosity, vertical and horizontal rated hydraulic conductivities, and unsaturat hydraulic characteristics which are express two pairs of parameters describing the rel ships between the degree of saturation and s pressure, and between the relative conduc and suction pressure, respectively. The results firm the common belief that overland flo creases for decreasing soil porosity or satu conductivity while the infiltration into the decreases. The effect of the ratio between ho tal and vertical saturated conductivity is insi cant, indicating the soil anisotropic effect is portant. Moreover, the overland flow dec and infiltration increases for soils having suction pressure head in the saturation and re conductivity vs. suction pressure relations corresponding, to, e.g. increasing soil particle than for soils having large suction pressure (Author's abstract)

for frequency analyses of annual floods
trial-and-error procedures for fitting the
on to a set of data. A procedure is de-
for direct, optimal fitting of the log-
n frequency distribution to either com-
plete sets or subsets of annual flood data. The analytical basis and derivation of the procedure are given. Annual floods from 65 yr of record on the 5,755-sq km Santa Cruz River at Tucson, Arizona, are used to show the fitting of the distribution to a complete data set, and annual floods from 24 yr of record on the 149-sq km Walnut Gulch watershed, in southeastern Arizona, are used to show the fitting of the distribution to a subset of data. Substantial differences between the log-Boughton and log-Pearson type 3 distributions occur in fitting to the Walnut Gulch data, due mainly to the large negative skew coefficient (-2.83) of this data set. The computer program which fits the log-Boughton distribution plots the data points on a probability paper which is automatically scaled to linearize the fitted distribution. Records with years of zero flow can be fitted directly without making arbitrary adjustments. (Moore-IVI)

ANALYTICAL DETERMINATION OF FORM FRICTION FACTOR,
George Washington Univ., Washington, DC. Dept. of Civil, Mechanical, and Environmental Engineering.
M. I. Haque, and K. Mahmood.
Journal of Hydraulic Engineering, Vol. 109, No. 4, p 590-610, April, 1983. 12 Fig, 1 Tab, 25 Ref. INT 76-84262.

Descriptors: *Friction, *Bedforms, Ripple marks, Dunes, Hydraulic roughness, Alluvial hydraulics, Steepness, Stream discharge, Streambeds.

The form friction factors for an idealized series of two-dimensional bedforms simulating a train of ripples or dunes in alluvial channels are obtained analytically by integrating the pressure along the bedform profiles. The roughness element is assumed to act independently so that the form friction factor can be obtained by analyzing the flow over a single bedform. The pressure distribution along the bedform is obtained by analyzing the incompressible, rotational inviscid flow over a theoretical ripple profile with the help of the Finite Element Method. A family of curves representing the relationship between form friction factor and relative depth with different bedform steepness ratios are numerically obtained. The comparison with the observed data shows a fair agreement. (Author's abstract)

DEVELOPMENT AND PREDICTION OF BED ARMORING,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
H. W. Shen, and J. Y. Lu.
Journal of Hydraulic Engineering, Vol. 109, No. 4, p 611-629, April, 1983. 14 Fig, 5 Tab, 19 Ref. ENG-78250554.

Descriptors: *Bed armoring, *Particle size, Dam effects, Sediment transport, Turbulence, Hiding effect, Mathematical models.

After the construction of a dam, the clear water released from the reservoir usually causes the downstream river to degrade. One critical ingredient for the successful application of mathematical models to the degradation problem is how to predict change of bed material size distribution during the degradation process and the final composition of the armoring layer. Available data are used to predict the development of bed armoring and the final composition of grain size distribution. First, the different factors influencing the incipient motion for nonuniform sediment size distribution are examined. Then, the procedures for simulating the grain size distribution of the armor layer are developed based on modifications of Gessler's procedure and Einstein's hiding factor. The final armor coat can be simulated reasonably well based on Gessler's procedure if: the Shields curve is slightly modified; the hiding effect is introduced; and the turbulence level is considered. Three regression equations are derived to predict the median size of the final armor bed, given the initial sediment bed size distribution and flow conditions. A modified Shields diagram for incipient motion for nonuniform sediment sizes is also suggested. (Moore-IVI)

MODELING OF UNSTEADY-FLOW WATER TEMPERATURES,
Old Dominion Univ., Norfolk, VA. Dept. of Civil Engineering.
M. H. Chaudhry, D. E. Cass, and J. E. Edinger.
Journal of Hydraulic Engineering, Vol. 109, No. 5, p 657-669, May, 1983. 8 Fig, 17 Ref.

Descriptors: *Water temperature, *Mathematical models, Simulation, River Flow, Lakes, Unsteady flow, Diversion, Columbia River, Kootenay River.

A mathematical model is presented to simulate water temperatures of one-dimensional unsteady flows in a river-lake system having time-varying lateral inflows and several cross-sectional changes along its length. In the hydraulic part initial steady state conditions are computed by numerically integrating the gradually-varied flow equation using the fourth-order Runge-Kutta method and the unsteady flow conditions by integrating the one-dimensional Saint Venant equations using an implicit finite difference method. An upwind implicit finite difference scheme is used to solve the partial differential equation governing the water temperature of unsteady flows. To verify the mathematical model, water temperature data on the Columbia and Kootenay Rivers measured during 1977 through 1979 were used. Overall, there was good agreement between the measured and computed water temperatures at almost all locations. There was also very good agreement between the shapes of the computed and measured traces. The model was used to predict the effects of the Kootenay River diversion on the temperature regime of the Columbia River. (Moore-IVI)

TURBULENT FLOW OVER UNDULAR PERMEABLE BOUNDARIES,
Exxon Research and Engineering Co., Florham Park, NJ.
R. T. Ho, and L. W. Gelhar.
Journal of Hydraulic Engineering, Vol. 109, No. 5, p 741-756, May, 1983. 9 Fig, 1 Tab, 23 Ref. GK31774X.

Descriptors: *Turbulent flow, *Boundary permeability, Pipe flow, Undulation, Boundary pressure, Velocity, Wave form, Wavy pipes.

The interaction between turbulent flow and compliant confining boundaries often generates wavy interfaces which eventually modify the flow characteristics significantly. This is a common phenomenon in many natural flows, including: the formation of various bedforms in alluvial channels; the generation of water waves by wind; the growth of ripples on the underside of river ice; and the production of sand dunes in deserts. The effects of boundary permeability and undulation in turbulent pipe flow are observed in an air flow conduit lined with a granular permeable material. Boundary pressure, mean velocity distribution, and longitudinal turbulence intensity were measured at several sections along the sinusoidal boundary. The observed boundary pressure shows a phase shift relative to the boundary wave form and a magnitude similar to that found from a simple potential flow analysis. The mean velocity distributions differ drastically from those observed in impervious wavy pipes, implying an important effect of the aspiration from the porous boundary in the lee of the wave form. The observations of turbulence intensity show that boundary permeability dramatically alters the turbulence structure as compared to an impervious wavy pipe. In the permeable pipe, a zone of high intensity turbulence develops in the

lee of the boundary wave form and expands to the central portion of the pipe. For impervious wavy pipes, the high turbulence intensity occurs only near the boundary as in the case of a straight pipe. (Moore-IVI)

Journal of Hydraulic Engineering, Vol. 109, No. 5, p 757-763, May, 1983. 4 Fig, 13 Ref.

Descriptors: *Suspended sediments, *Velocity, Flow resistance, Mathematical models, Wake function, Boundary conditions.

A general velocity distribution consisting of a logarithmic profile plus a wake function has been used to investigate the effect of suspended sediment on flow resistance. From the experimental evidence that the wake constant increases when sediment is in suspension, it is shown that flow resistance must be reduced. It is shown that a flow with suspended sediments should have lower velocities near the boundary and higher velocities further away from the boundary than a clear water flow, given that the discharge and slope are identical. IMPROVED FLOODPLAIN MANAGEMENT CAN BE COST-EFFECTIVE,
J. A. Biggs.
American City and County, Vol. 98, No. 4, p 43-44, April, 1983. 1 Fig.

Descriptors: *Flood control, *Flood plain management, Photography, Aerial photography, Passaic River, River basins, New Jersey.

An estimated annual flood damage figure of $48 million makes the Passaic River Basin the more serious flood zone in New Jersey. The Rockaway River, a stream within the basin, drains 95 sq mi before entering Denville Township. In the township virtually the entire riverfront is subject to flooding. Documentation of the January 25, 1979 flood provided a data base for future floodplain management activities. Aerial and ground level photographs, along with a rough log that showed the times they were taken, formed the basic data for analyzing the floodplain within the township. The photo records were then transformed to engineering-type data through a land survey. After the study was completed it was used by the township in several ways: it formed the basis for a formal objection to the state Department of Environmental Protection concerning that agency's preliminary revision of the 1975 HUD/FIA map; it is used continuously by the engineering department to evaluate the flooding potential of existing and proposed houses; it is used to make decisions involving floodplain property; it has been a basic reference tool whenever the township considers such project as road construction and the construction of senior citizens' housing, municipal buildings, museums, libraries and other buildings; and photographs from the study have been introduced as evidence in municipal court to prove the floodplain status of properties where illegal fill has been placed. PARAMETER ESTIMATION IN RAINFALL-RUNOFF MODELS,
Newcastle Univ. (Australia).
B. J. Williams, and W. W-G. Yeh.
Journal of Hydrology, Vol. 63, No. 3-4, p 373-393, June, 1983. 8 Fig, 8 Tab, 27 Ref. NSF grant CEE 81-13500.

Descriptors: *Rainfall-runoff relationships, *Error analysis, Mathematical models, Linear programming, Quadratic programming, Computer models.

In the practical application of rainfall-runoff models a number of catchment parameters are not directly measurable and it is desirable to make the best possible estimate from known rainfall-runoff data. Linear programming (LP) is used to minimize the sum of absolute errors (MSAE) of the computed hydrograph. Quadratic programming (QP) is used in the two other techniques, namely ordinary least squares (OLS) and generalized least squares (GLS). OLS uses the traditional regression objective of minimizing the square of the deviation while GLS uses a weighted form of the OLS objective which can eliminate the effect of serially correlated errors (noise). The techniques are demonstrated using a hypothetical catchment for which rainfall-runoff series are generated using a connceptual model. Four parameters necessary for the model's operation are then estimated, with varying levels of noise superimposed on the generated series, using the three techniques and then finally the techniques are applied to a real catchment. The computational efficiency and rate of convergence were demonstrated to be good. The proposed methodology is very general and it can be applied to any conceptual rainfall-runoff model. The GLS technique has proven superior to the traditional OLS technique and would appear to be preferable in practical estimations. (Moore-IVI)

WAVE SPEED-DISCHARGE RELATIONS IN NATURAL CHANNELS,
Monash Univ., Clayton (Australia). Dept. of Civil Engineering.
T. H. F. Wong, and E. M. Laurenson.
Water Resources Research, Vol. 19, No. 3, p 701-706, June, 1983. 8 Fig, 2 Tab, 9 Ref.

Descriptors: *Flood waves, *Velocity, Flood discharge, Mathematical studies, Flood routing, Runoff routing, Murrumbidgee River, Darling River, Mitta Mitta River, Australia.

An important parameter in flood routing is the speed at which the flood wave travels along the river reach. Empirical studies of wave speed for six reaches of the Murrumbidgee, Darling and Mitta Mitta rivers in Australia show that wave speed at first increases quickly with discharge, then decreases quickly, and finally increases slowly. The increasing parts of the relation can be fitted by power functions with exponents less than unity. Minimum wave speed occurs close to bank-full discharge. These results have a direct application to storage-discharge relations and important implications in flood routing and runoff routing. (Moore-IVI)

SIMULATION OF SOLUTE TRANSPORT IN A MOUNTAIN POOL-AND-RIFFLE STREAM: A TRANSIENT STORAGE MODEL,
Geological Survey, Menlo Park, CA.
K. E. Bencala, and R. A. Walters.
Water Resources Research, Vol. 19, No. 3, p 718-724, June, 1983. 8 Fig, 1 Tab, 25 Ref.

Descriptors: *Mountain streams, *Solute transport, Streams, Simulation, Mathematical models, Transient storage, Pools, Riffles, Convection, Dispersion, Chloride.

The physical characteristics of mountain streams differ from the uniform and conceptually well-defined open channels for which the analysis of solute transport has been oriented in the past and is now well understood. These physical conditions significantly influence solute transport behavior, as demonstrated by a transient storage model simulation of solute transport in a very small (0.0125 cu m/s) mountain pool-and-riffle stream. The application is to a carefully controlled and intensively monitored chloride injection experiment. The data from the experiment are not explained by the standard convection-dispersion mechanisms alone. A transient storage model, which couples dead zones with the one-dimensional convection-dispersion equation, simulates the general characteristics of the solute transport behavior and a set of simulation parameters were determined that yield an adequate fit to the data. However, considerable uncertainty remains in determining physically realistic values of these parameters. The values of the simulation parameters used are compared w used by other authors for other streams T parison supports, at least qualitatively, th mined parameter values. RUNOFF PREDICTION ERRORS AND IN PARAMETER ESTIMATION INDUC SPATIAL VARIABILITY OF PRECIPITA
Geological Survey, Menlo Park, CA.
B. M. Troutman.
Water Resources Research, Vol. 19, No. 3, 810, June, 1983. 12 Fig, 13 Tab, 27 Ref.

Descriptors: *Rainfall-runoff relationships, analysis, *Mathematical models, Precipitatio chastic methods, Spatial variability, Pre Rainfall distribution.

Spatial variability of precipitation causes i mean squared errors of prediction in precip runoff modeling. One component of these errors is a bias, which often takes the form o prediction for large events and underpredict small events. This problem is examined us assumed stochastic structure for the spatial ior of rainfall together with a form of the Ampt infiltration equation for prediction of runoff volume. The stochastic rainfall model porates the nonstationarity and spatial corr exhibited by actual rainfall. The bias in prediction causes parameter estimates obtai least squares calibration to be asympto biased. The magnitude and direction of th depends on the interaction between the prediction bias and the sensitivity of pre runoff to changes in parameter values. Nu climatic and hydrologic factors exercise an ence on this interaction. (Author's abstract)

of regime, discharge variability and reces-
flow from peak discharge in the rainy
the lowest discharge in the dry season.
ximum and minimum discharges of the
oincide with the rainy and dry seasons
ely. Most of the rivers exhibit erratic flow
ck responses to storms and storm water
quickly, while some have a very low
ater contribution to streamflow, a phe-
which accounted for their drying up for
able periods in the year. The variability
f discharge of the rivers range from 0.25
while the recession constants range from
0.98. The variability indices are much
an those of basins of similar size reported from other studies. Three types of rivers are recognizable on the basis of their hydrological response patterns: rivers characterized by perennial flow, low variability of discharge, and gentle recession of flow from peak discharge in the rainy season to minimum discharge in the dry season; rivers with high discharges during the rainy season but which dry up completely for between 100 and 150 days in the dry season; and seasonal rivers which dry up for between 190 and 270 days in the year. The nature of the surficial and solid geology has a greater influence on discharge characteristics than other factors such as depth of regolith and rainfall. (Moore-IVI)

ON BACKWATER EFFECTS IN LINEAR DIFFUSION FLOOD ROUTING,
University Coll., Dublin (Ireland). Dept. of Civil Engineering.
J. C. I. Dooge, Z. W. Kundzewicz, and J. J. Napiorkowski.
Hydrological Sciences Journal, Vol. 28, No. 3, p 391-402, September, 1983. 2 Tab, 10 Ref.

Descriptors: *Flood routing, *Linear diffusion, *Boundary conditions, *Downstream, Mathematical models, Laplace transformation, Modal analysis.

The linear parabolic model of unsteady river flow (diffusion analogy) has the advantage of being a simple means of flood routing. The effect of the downstream boundary condition on the flow in a channel reach as predicted by the linear diffusion analogy model is analyzed by both Laplace transformation and by modal analysis. In each case the solution takes the form of an infinite series. The series based on Laplace transformation is highly convergent for small times and the series based on modal analysis is highly convergent for medium and longer times. (Moore-IVI)

AQUIFER TESTS AND WELL FIELD PERFORMANCE, SCIOTO RIVER VALLEY, OHIO: PART I,
S. E. Norris.
Ground Water, Vol. 21, No. 3, p 287-292, May-June, 1983. 2 Fig, 3 Tab, 11 Ref.

Descriptors: *Aquifer characteristics, *Infiltration, Transmissivity, Streambeds, Pumping, Drawdown, Scioto River, Ohio.

Based on 13 aquifer infiltration tests at 11 sites, aquifer transmissivity ranged from 17,000 to 40,000 sq ft per day, and the streambed infiltration rate ranged from 0.06 to 0.19 million gallons per day per acre along a 7-mi reach of the Scioto River in south-central Ohio. Despite these wide ranges, the sand and gravel aquifer, 40 to 65 ft thick, underlying 10-20 ft of river alluvium south of the glacial boundary, is fairly homogeneous due largely to the absence of till interbeds. Performance of a major well field designed on the basis of the tests has been about as predicted, validating the techniques of data collection and analysis. At each site, a well for pumping was drilled on the floodplain, 150 to 175 ft from the river, and an array of observation wells was installed on lines extending through the pumped well, one line perpendicular to the river and the other parallel. Values of drawdown measured in the observation wells at the end of constant-rate pumping periods, usually of three days duration, were used to determine line-source distance and aquifer transmissivity. The rate of streambed infiltration and the streambed-leakage factor, the latter term relating the infiltration rate to drawdown beneath the stream, also were determined at all but one site. Drive-point wells installed in the riverbed, or along the near bank, in the vicinity of the pumped well were used to determine drawdown beneath the river due to pumping. (Author's abstract)

GROUND-WATER MODEL FOR A THICK FRESH-WATER LENS,
Hawaii Univ. at Manoa, Honolulu. Dept. of Civil Engineering.
C. C. K. Liu, L. S. Lau, and J. F. Mink.
Ground Water, Vol. 21, No. 3, p 293-300, May-June, 1983. 10 Fig, 2 Tab, 12 Ref.

Descriptors: *Groundwater, *Freshwater lens, Aquifers, Groundwater movement, Simulation, Pumping, Pumping, Mathematical models, Groundwater recharge, Pearl Harbor aquifer, Oahu, Hawaii.

The Pearl Harbor aquifer, an important groundwater resource for southern Oahu, Hawaii, contains an enormous fresh-water lens, up to 300 m (1,000 ft) thick, floating above saline water. The upper boundary of the fresh-water lens is confined near the coast and phreatic inland, whereas its lower boundary is not confined. A finite-difference flow model was used to simulate the Pearl Harbor aquifer system. The location of the fresh-water / salt-water interface, which constitutes the lower boundary of the flow system model, was estimated by Hubbert's formula. Known geohydrologic boundaries and aquifer parameters were also simulated. First, formation of the lens by filling the aquifer with fresh water from natural recharge was simulated to reconstruct the initial conditions before exploitation of the lens and to partially calibrate the model against the hydraulic-head distribution in 1879. The model then was calibrated fully by simulating the lens' response to actual historical pumping patterns covering a time span of 100 years (1880 to 1980). Simulated heads compared favorably with the observed heads over time and space. The calibrated flow model may serve as a useful tool in the management of the Pearl Harbor aquifer. (Author's abstract)

GROUND-WATER SYSTEMS SIMULATION BY TIME-SERIES TECHNIQUES,
Aspinwall Hydrotechnical Services Ltd., Shrewsbury (England).
J. F. T. Houston.
Ground Water, Vol. 21, No. 3, p 301-310, May-June, 1983. 10 Fig, 6 Tab, 9 Ref.

Descriptors: *Simulation, *Groundwater, Time-series, Hydrologic budget, Pumping rates, Geohydrology, Mathematical models, Rainfall, Mine dewatering, Groundwater management, Water level fluctuations.

The application of time-series techniques to groundwater problems is a logical extension of the water balance approach, allowing a water balance equation to become dynamic and thus simulating a groundwater system in time. The basic time-series techniques are considered in relation to hydrogeology and two case histories show their application to real systems. Water level fluctuations in a well field are shown to be dependent upon pumping rates and prior rainfall and can be simulated by a multiple linear regression model. The rate of dewatering of a mine is shown to be dependent upon pumping rates and prior rainfall and can be simulated by a multiple linear regression model. The rate of dewatering of a mine is shown to be dependent upon antecedent mine size and rainfall, and can also be simulated by a multiple linear regression model. Such models can be used for forecasting and control of the groundwater systems, and once formulated are ideally suited to the management of groundwater systems where more costly and complex methods cannot be used. PORE-WATER PRESSURE IN THE ROOF OF AN UNDERGROUND COAL MINE IN ILLINOIS,
Illinois State Geological Survey Div., Champaign.
K. Cartwright, C. S. Hunt, R. D. Brower, and W. J. Nelson.
Ground Water, Vol. 21, No. 3, p 311-316, May-June, 1983. 4 Fig, 11 Ref.

Descriptors: *Pore pressure, *Mine drainage, Coal mines, Permeability coefficient, Groundwater, Geohydrology, Water table, Stratigraphy.

Most underground coal mines in Illinois are relatively dry despite their location in saturated rock lying hundreds of meters below the water table. This is probably due to the low permeabilities of the rock units associated with the coal seams. Little is known about how mines affect the groundwater system, so it is difficult to predict where a mine is likely to encounter an influx of ground water. To obtain information on the hydrogeological character of the roof rocks, an array of piezometers was installed in roof-bolt holes at two locations within an underground coal mine in central Illinois. Pressure vs. time measurements were obtained from piezometer arrays located in areas of the mine ranging from dry to wet conditions. Data collected from the piezometers indicate that water drainage from a saturated sandstone above the coal is largely controlled by local structural and stratigraphic features, and these features determine the distribution of wet and dry areas in the mine. Hydraulic conductivities of the sandstone were determined in the laboratory and in situ from drainage profiles and from tests of instantaneous head changes. Results of these tests indicated that dewatering in front of mining would not be successful in this mine. (Author's abstract)

HYDROGEOLOGY OF THE LITTLEFIELD SPRINGS, ARIZONA,
Bureau of Reclamation, Boulder City, NV.
D. A. Trudeau, J. W. Hess, and R. L. Jacobson.
Ground Water, Vol. 21, No. 3, p 325-333, May-June, 1983. 7 Fig, 3 Tab, 12 Ref.

Descriptors: *Groundwater recharge, *Geohydrology, *Springs, Tritium, Water quality, Littlefield Springs, Virgin River, Arizona.

A hydrogeologic investigation was conducted to determine the source of recharge to the Littlefield Springs, a series of carbonate springs occurring along a 10 km (6 mile) reach of the Virgin River in northwestern Arizona. The most probable sources of recharge to the springs were determined to be influent Virgin River water and precipitation within the springs by hydrologic basin. These recharge sources could account for the total discharge of the springs. The Littlefield Springs have essentially constant discharge 1.84 cms (65 cfs), and quality 2940 mg/L TDS. Tritium analyses of the spring and river water indicate that there are at least two different sources of recharge to the Littlefield Springs - one a minimum of 22 years old and the other younger than 22 years old. Analysis of the influent Virgin River upstream from the springs indicates a 1.42 cms (50 cfs) loss at 2130 mg/L TDS and the same ionic ratio of dissolved constituents as the springs. The travel time of this recharge source is interpreted to be a minimum of 22 years. Local recharge to the springs has been estimated to be 0.31 cms (11 cfs). The presence of local recharge is indicated by pulse train gaging of the springs, and by water quality at a well upstream of the springs and at the first upstream occurrence of the springs. The travel time of this recharge source is interpreted to be less than 22 years. (Author's abstract)

GEOPHYSICAL LOGGING IN CARBONATE AQUIFERS,
Geological Survey, Spokane, WA. Water Resources Div.
L. M. MacCary.
Ground Water, Vol. 21, No. 3, p 334-342, May-June, 1983. 15 Fig, 8 Ref.

Descriptors: *Logging (recording), *Aquifers, Well logs, Limestone, Dolomite, Porosity, Water quality, Resistivity, Groundwater recharge, Groundwater movement, Water temperature, Saline water.

Some logging methods are inherently superior to others for the analysis of limestone and dolomite aquifers. Three such systems are the density, neutron, and acoustic-velocity logs. Relative percentages of limestone and dolomite, average matrix (grain) densities of the rock mixtures, and porosity of the rock mass can be calculated from density, neutron, and acoustic-velocity logs. Wells drilled before the 1960's generally were logged with an uncalibrated neutron tool. In some instances, the resultant curve can be empirically calibrated. With supporting data from resistivity logs, apparent water resistivity (Rwa) can be estimated. Depending on rock and mud resistivities, the two most useful resistivity curves for water quality studies are the deeply-focused laterolog and the induction log. For older wells, the standard electric log may be used, if the drilling mud is not salt-saturated. Rwa contour maps derived from geophysical data are useful to outline areas of recharge, direction of probable groundwater flow, and location and salinity of brine areas. Another useful application of well logs is estimation of ground-water temperature. These temperatures are obtained from maximum-reading thermometer data that generally are recorded on each logging run. Maps of porosity can be used to outline potential areas for completing large-yield wells. (Author's abstract)

GROUNDWATER RECHARGE THROUGH A HEAVY-TEXTURED SOIL,
Department of Agriculture, Lethbridge (Alberta). Irrigation Div.
M. J. Hendry.
Journal of Hydrology, Vol. 63, No. 3-4, p 201-209, June, 1983. 5 Fig, 11 Ref.

Descriptors: *Groundwater recharge, *Soil water, *Soil texture, Tritium, Tracers, Particle size, Fracture permeability, Fracture flow, Intergranular seepage, Alberta, Water table.

A testhole was cored to a depth of 17.4 m ground surface in southern Alberta, Canad 55 samples were collected from the cores at intervals. The soil water was distilled from sample and analyzed for natural tritium and t samples were analyzed for particle-size di tion. The upper 3 m of the stratigraphic s consists of coarse to heavy-textured interb lacustrine deposits. These units are underlai heavy-textured weathered till. The site is a z groundwater recharge with the water table below the ground surface. Water, which e the subsurface environment from ground after 1953, has migrated to the lacustrine-til tact via intergranular seepage and fracture and fractures are transmitting post-1953 re water to depths within the underlying slowl meable unsaturated and saturated till. The or a broad tritium peak immediately below the table may be the result of an increasing fr density at this depth. In addition, diffusion tium from the fractures into the adjacent material appears to occur both above and the water table. (Moore-IVI)

ooley.
Resources Research, Vol. 19, No. 3, p 662- e, 1983. 22 Fig, 5 Tab, 10 Ref.

Descriptors: *Groundwater movement, *Mathematical models, Nonlinear regression, Errors, Water level, Nevada, Washoe County, Truckee Meadows.

In projects involving groundwater modeling, two independent numerical data sets normally exist: a set of water level observations, called sample information, and a set of measurements or calculations of the system parameters, called prior information. Factors influencing the degree of improvement in estimates of parameters of a nonlinear regression groundwater flow model by incorporating prior information of unknown reliability were investigated. If the parameters are properly scaled, linearized expressions for the mean square error (MSE) in parameter estimates of a nonlinear model will often behave very nearly as if the model were linear. By using prior information, the MSE in properly scaled parameters can be reduced greatly over the MSE of ordinary least squares estimates of parameters. Plots of estimated MSE and the estimated standard deviation of MSE versus an auxiliary parameter (the ridge parameter) specifying the degree of influence of the prior information on regression results can help determine the potential for improvement of parameter estimates. Proposed criteria can be used to make appropriate choices for the ridge parameter and another parameter expressing degree of overall bias in the prior information. Results of a case study of Truckee Meadows, Reno-Sparks area, Washoe County, Nevada, conform closely to the results of the hypothetical problem. In the Truckee Meadows case, incorporation of prior information did not greatly change the parameter estimates from those obtained by ordinary least squares. Both sets of estimates are more reliable than suggested by the standard errors from ordinary least squares. (Moore-IVI)

Descriptors: *Permeability, *Hydraulic head, *Groundwater, Mathematical modeling, Simulation, Geostatistics, Geohydrology.

The problem of estimating hydrogeologic parameters, in particular, permeability, from input-output measurements is reexamined in a geostatistical framework. The field of unknown parameters is represented as a 'random field' and the estimation procedure consists of two main steps. First, the structure of the parameter field is identified, i.e. mathematical representations of the variogram and the trend are selected and their parameters are established by using all available information, including measurements of hydraulic head and permeability. Second, linear estimation theory is applied to provide minimum variance and unbiased point estimates of hydrogeologic parameters (kriging). Structure identification is achieved iteratively in three substeps: structure selection, maximum likelihood estimation, and model validation and diagnostic checking. The methodology was extensively tested through simulations on a simple one-dimensional case. The results are remarkably stable and well behaved. The estimated field is smooth, while small-scale variability is statistically described. As the quality of measurements improves, the procedure reproduces more features of the original field. The results are also shown to be rather insensitive to deviations from assumptions about the geostatistical structure of the field. (Author's abstract)

Water Resources Research, Vol. 19, No. 3, p 753-767, June, 1983. 22 Fig, 5 Tab, 34 Ref. DOE contract DE-AC03-76SF00098.

Descriptors: *Geothermal resources, *Mass transfer, *Heat, Mathematical models, Simulation, Groundwater recharge, Computer models, Cerro Prieto Geothermal Field, Mexico.

Numerical simulation techniques are employed in studies of the natural flow of heat and mass through the Cerro Prieto reservoir, Mexico and of the effects of exploitation on the field's behavior. The reservoir model is a two-dimensional vertical east to west-southwest cross section, which is based on a recent hydrogeologic model of this geothermal system. The numerical code MULKOM is used in the simulation studies. The steady state pressure and temperature distributions are computed and compared against observed preproduction pressures and temperatures: a reasonable match is obtained. A natural hot water recharge rate of about 0.001 kg/s per meter of field length (measured in a north-south direction) is obtained. The model is then used to simulate the behavior of the field during the 1973-1978 production period. The response of the model to fluid extraction agrees to what has been observed in the field or postulated by other authors. There is a decrease in temperatures and pressures in the produced region. No extensive two-phase zone develops in the reservoir because of the strong fluid recharge. Most of the fluid recharging the system comes from the colder regions located above and west of the produced reservoir. (Author's abstract)

EFFICIENT FINITE ELEMENT TECHNIQUE FOR MODELING TRANSPORT IN FRACTURED POROUS MEDIA; 1. SINGLE SPECIES TRANSPORT,
GeoTrans, Inc., Reston, VA.
P. S. Huyakorn, B. H. Lester, and J. W. Mercer.
Water Resources Research, Vol. 19, No. 3, p 841-854, June, 1983. 15 Fig, 5 Tab, 21 Ref. DOE contract E512-02900.

Descriptors: *Solute transport, *Porous media, *Geologic fractures, Mathematical models, Simulation, Differential equations, Diffusion.

A mathematical model is presented for numerical simulation of solute transport in naturally fractured porous media. The model is based on the dual-porosity conceptual approach and is capable of simulating interactions between porous rock matrix and fractures. Unlike earlier dual-porosity transport models, which rely on parallel fracture assumptions, the present model is a unified model that is also able to represent blocky fractured systems (i.e., systems with suborthogonal fractures) by using a spherical idealization of matrix blocks. Two governing, partial differential equations are written for solute transport in the fractures and diffusion in the porous matrix blocks. These equations are coupled by mass flux terms (leakages). An efficient numerical scheme is presented for approximating the governing transport equations. The scheme effectively combines a two-dimensional, upstream-weighted, finite-element approximation for transport in the fractures with a one-dimensional Galerkin approximation for diffusion within the individual matrix blocks. Coupling of the two approximations is performed implicitly. The systems of algebraic equations resulting from both finite-element approximations are solved by using sequential solution algorithms designed especially for this type of problem. Stability and accuracy of the numerical scheme are checked by applying the model to a number of test problems and comparing results with available analytical

solutions. In all cases the numerical scheme is found to be highly stable and capable of producing reliable results with the use of relatively coarse spatial and temporal discretizations. Finally, the utility of the model is demonstrated by applying it to a hypothetical, yet realistic, problem. (Author's abstract)

EXTRACTION AND CHEMICAL ANALYSIS OF INTERSTITIAL WATER FROM SOILS AND ROCKS,
Institute of Geological Sciences, London (England). Hydrogeology Unit.
D. G. Kinniburgh, and D. L. Miles.
Environmental Science and Technology, Vol. 17, No. 6, p 362-368, June, 1983. 2 Fig, 7 Tab, 19 Ref.

Descriptors: *Interstitial water, *Soil water, Chalk, Solutes, Chemical analysis, Clays, Organic carbon, Spectrometry, Topsoil.

Interstitial water was extracted from field-moist soils and chalk by immiscible displacment with a dense, inert fluorocarbon liquid. The only special equipment required is a high-speed centrifuge. Yields of interstitial water from soils at field capacity are typically 20-50% of the total water present; yields from chalk range up to 90%. The interstitial water was analyzed for about 20 solutes principally by inductively coupled plasma emission spectrometry. The water extracted from a chalk sample appeared to be representative of all the water present, but with a clay soil, there was evidence of some fractionatiion of NO3-N. Organic carbon (0.002 to 0.007 M) was frequently the most abundant solute in the solutions extracted from ten topsoils. Other typical solute concentrations were in the range 0.001 to 0.0001 M for NO3-N, Na, Mg, Si, S, Cl, K, and Ca and less than 0.000001 M for the trace elements Cu, Zn, and Ba. (Author's abstract)

COMPETITIVE ADSORPTION DURING SOLUTE TRANSPORT IN SOILS: 1. MATHEMATICAL MODELS,
Western Australia Univ., Nedlands. Dept. of Soil Science and Plant Nutrition.
V. Murali, and L. A. Aylmore.
Soil Science, Vol. 135, No. 3, p 143-150, March, 1983. 22 Ref.

Descriptors: *Leaching, *Mathematical models, *Solute transport, Adsorption, Soil-water-plant relationships, Competitive adsorption, Isotopic exchange, Convection, Dispersion.

One-dimensional, convective-dispersive-adsorptive flow models, in Cartesian and polar coordinates, representing flow of chemicals in soils (e.g., leaching) and toward plant roots, are generalized to competitive multispecies systems. Langmuir-type competitive adsorption models suitable for equilibrium and dynamic interactions are presented, and a few special simplified cases are discussed. Freundlich-type equilibrium adsorption models are modified to multispecies situations. An empirical approach, capable of handling most general equilibrium adsorption isotherms, suitable for multispecies systems, is also described. The empirical approach is comparable to equilibrium Langmuir and Freundlich-type competition in binary systems. Isotopic exchange, which is a form of competition between isotopes of the species for adsorption or exchange sites, may be described through a simple McKay-type equation. (Author's abstact)

ESTIMATING SOIL MOISTURE STORAGE IN THE ROOT ZONE FROM SURFACE MEASUREMENTS,
Computer Sciences Corp., Silver Spring, MD.
P. Camillo, and T. J. Schmugge.
Soil Science, Vol. 135, No. 4, p 245-264, April, 1983. 18 Fig, 9 Tab, 21 Ref.

Descriptors: *Soil water, *Mathematical models, *Simulation, *Roots, Soil water suction, Soil texture, Root zone, Remote sensing, Matric suction profile.

Numerical simulations of the dynamics of soil water in the root zone of a vegetated field show that the matric suction profile can eventually acquire the same shape as the relative root density profile. The suction at any depth is proportional to the corresponding root density raised to a power that depends on soil texture. This behavior is found only for fully grown root systems when the soil water distribution is controlled primarily by the water absorption by the roots; this becomes more likely as the soil dries out. That this power law is a solution of the continuity equation will also be demonstrated analytically. This functional relationship is used to show that, under these restrictive conditions, root zone soil moisture storage is a linear function of volumetric moisture at a particular depth, with the slope changing with depth but fixed in time. This hypothesis is supported by both laboratory and field soil moisture profile measurements, which were taken in fields with fully grown plants. No other model parameters need to be estimated, and the good agreement found constitutes an independent validation of the soil water extraction model under the plant and soil conditions described. Potential applications of these results include estimating soil moisture storage in the root zone from remotely sensed surface soil moisture and estimating the root profile from matric potential profile measurements. Descriptors: *Soil-water-plant relationships, *Mathematical models, *Water uptake, *Roots, Soil water, Boundary conditions, Rainfall, Evaporation, Transpiration, Soil saturation.

A transient one-dimensional finite-difference model for the unsaturated zone with water uptake by roots is presented. A number of boundary conditions is given for the top and the bottom of the system. At the top, 24-hr. data on rainfall, potential soil evaporation and potential transpiration are needed. When the soil system remains unsaturated, one of the three bottom boundary conditions can be used: pressure head, zero flux or free drainage. When the lower part of the system remains saturated, one can either give the groundwater level or the flux through the bottom of the system as input. In the latter case the groundwater level is computed. (Author's abstract)

Spatial distribution, Crop yield, Soil hydraulic
Statistical methods, Geostatistics.

A geostatistical approach was used to investiga
the spatial variability of two measured soil hydra
lic parameters, the saturated hydraulic conductiv
ity Ks and alpha = d(log K(h))/(d(h)), where K
the hydraulic conductivity and h is the soil wate
pressure head. Using a linearized solution to stead
infiltration from a circular shallow pond, the spa
tial distribution of the midway soil water pressu
head between emitters, he (for a given trickl
discharge rate Q and spacing between emitters, d
was calculated using the spatially variable soil pa
rameters K, and alpha. The spatial distribution o
the crop yield Y was calculated from the spatiall
variable he by using a quadratic expression of th
Y(he) relationships. It was found that the spati
variability of each of the measured input paran
eters (Ks and alpha) or the calculated output vari
bles (he and Y) is expressed through the variogra
gamma and can be characterized in terms of th
coefficient of variation CV and the integral scale
In the case of log Ks, for which the sill is reache
at relatively small range, two different gamma
were tested. Results showed that the kriged valu
of log Ks as well as the resultant values of he
he(Ks alpha; d, Q) were relatively insensitive t
the selected gamma. The spatial variability of h
reduced the average (over the field) crop yield th
would have been obtained when he was uniform
throughout the field. The spatially variable so
parameters Ks and alpha were used to calculate th

l distribution of the spacing between emitters equired to achieve (for a given trickle dis-e) a prespecified value of he uniform ghout the field. It was found that the use of a lly variable d increased the field crop yield % relative to the yield that was obtained when le-valued d uniform throughout the field was The spatial distribution of d was combined hydraulic principles to derive the spatial dis-ion of lateral diameter and length for engi-ng design requirements. through curves (BTC's) of tritiated H2O and simultaneously displaced through columns of us-sized aggregates of an Ione Oxisol soil measured under water-saturated steady flow ions. The data were simulated using two ptual models. In model I, all soil water was ed to be mobile with a physical equilibrium g in the system. For model II, soil water was oned into mobile and immobile regions. Con-e diffusive solute transport was limited to the e water region. Transfer of a tracer between o soil water regions was assumed to occur at proportional to the difference in tracer con-tions between the two regions. Sorption of d H20 and Cl36 was considered to be an taneous linear and reversible process. The nknown parameters in model I and the four wn parameters in model II were estimated ing model predictions to the experimental Model I could only describe BTC's obtained columns packed with small aggregates (0.5-1 nd for displacements run at small fluxes (0.2 , whereas model II described all the BTC's Peclet numbers P in model II, as measured on separate column, were essentially constant, ing a linear relationship between the appar-ffusion coefficient D and the mobile pore velocity vm. The fraction of soil water that bile, phi, and the mass transfer coefficient were found to be a function of the physical hemical properties of the porous medium gate size, pore water velocity, and solution ntration). raphic effects, soil heterogeneity, and spatial lity in precipitation and vegetation may variability in measured soil moisture. Scal-eory has been suggested as a promising tool scribing soil heterogeneity and, consequent-ortion of spatial variability of measured soil re. The appropriateness of ascribing soil re variability to heterogeneity of soil prop-s investigated through the use of a model of oisture dynamics and scaling theory. The termed a wetting front model, is a simpli-epresentation of water movement in soils. The model conceptually depicts the moisture profile as discrete blocks of soil moisture separated by sharp fronts. Probabilistic simulations were run with input data appropriate to watersheds R-5 and R-7 at Chickasha, Oklahoma. Variability due to soil heterogeneity remains relatively constant through time with only slight increases during redistribution following infiltration. A comparison of simulated and observed soil moisture integrated from the surface to the 15-cm depth shows that heterogeneity in soil hydraulic properties may account for approximately 75% of observed standard deviation, or 56% of the variance. By ascribing all of the uncertainty in a soil system to scaled differences in the soil matrix, one may be limiting the mathematical simulator to a certain pattern in the variability in the computed moisture content. RAINWATER INFILTRATION INTO A BARE LOAMY SAND,
Central Arid Zone Research Inst., Jodhpur (India).
K. D. Sharma, H. P. Singh, and O. P. Pareek.
Hydrological Sciences Journal, Vol. 28, No. 3, p 417-424, September, 1983. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Infiltration, *Rainfall, *Rainfall impact, *Slope, Soil surfaces, Water harvesting, Slope length, Loamy sand, India.

In order to design micro-catchment water harvesting systems in the Indian desert, rainwater infiltration experiments were conducted on a representative loamy sand soil for a period of six years. Plots with three slopes - 0.5, 5 and 10%, and five slope lengths - 5.12, 7.0, 8.5, 10.75 and 14.5 m were used. With dry antecedent soil conditions, infiltration is governed by rainfall depth, whereas with wet antecedent soil conditions, raindrop impact (intensity) which forms a crust over the soil surface, is the deciding factor. Infiltration decreases significantly with increasing slope due to reduction in the time available for rainfall to infiltrate, but slope length has no significant effect. A graphical multiple curvilinear model to predict rainfall infiltration using rainfall and basin characteristics is developed and the goodness of fit is tested. (Author's abstract)

DISTRIBUTION AND ABUNDANCE OF LARVAL BURBOT AND DEEPWATER SCULPIN IN LAKE MICHIGAN,
Michigan Univ., Ann Arbor. Great Lakes Research Div.
P. J. Mansfield, D. J. Jude, D. T. Michaud, D. C. Brazo, and J. Gulvas.
Transactions of the American Fisheries Society, Vol. 112, No. 2A, p 162-172, March, 1983. 5 Fig, 2 Tab, 42 Ref.

Descriptors: *Burbot, *Sculpin, *Larvae, *Lake Michigan, Spawning, Distribution, Entrainment, Water temperature, Fish populations.

Samples from seven locations at depths to 21 m, collected over periods of up to 8 years, were used to describe the nearshore distribution and abundance of burbot Lota lota and deepwater sculpin Myoxocephalus thompsoni larvae in Lake Michigan. Based upon power-plant-entrainment samples and field collections, burbot larvae (3.0-7.5 mm) occurred from late March to mid-June, most abundantly in April and May, and most often at water temperatures of 6-12 C. Larvae were collected from the 0.5- to 13.5-m depth strata as far lakeward as the 21-m bottom contour, the limit of offshore sampling. In eastern Lake Michigan, highest densities (up to 843 larvae/1,000 cu m) were at the 1-m contour; in Green Bay, up to 24,000 larvae/1,000 cu m were detected near the Bark River. High densities of burbot larvae at bottom depths 3 m and less indicated inshore spawning and river spawning at some sites. Deepwater sculpin larvae first occurred in early February and were common in March and April entrainment samples. Larvae (8.0-22.0 mm) were in nearshore waters usually through May at depth strata of 0.5 to 17 m as far lakeward as the 18-m bottom contour. Most larvae occurred at water temperatures below 6 C. Field densities were low, 5 to 78 larvae/1,000 cu m. Deepwater sculpin larvae were pelagic and were dispersed over great distances by currents. (Author's abstract)

DIEL DRIFT AND FEEDING OF CHANNEL CATFISH ALEVINS IN THE ILLINOIS RIVER, ARKANSAS,
Arkansas Game and Fish Commission, Hot Springs.
M. L. Armstrong, and A. V. Brown.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 302-307, March, 1983. 1 Fig, 1 Tab, 35 Ref.

Descriptors: *Fish, *Larvae, *Drift, *Fish food, Catfish, Alevins, Invertebrates, Midges, Water currents, Illinois River, Arkansas.

The downstream displacement, or drift, of fish larvae in lotic ecosystems has, in addition to its intrinsic interest, practical importance whenever withdrawals of water are contemplated for industrial or other uses. It is not clearly understood why larval fish drift, but it has been suggested that the fish are feeding on drifting invertebrates. The food habits of 317 channel catfish Ictalurus punctatus alevins (standard length 14-16 mm) collected from the Illinois River, Arkansas were investigated to determine if the drifting alevins were using drifting invertebrates as a food resource. Drift of alevins coincided with increases in fullness of their stomachs, but alevins had been feeding predominantly on chironomid larvae and pupae, which were rare in the drift and riffle substrate. Alevins apparently fed on chironomids in upstream pools and accidentally encountered swift currents that caused them to drift downstream. If so, drift was a consequence of feeding activity, not an aid to it. (Moore-IVI)

SPAWNING AND EARLY-LIFE ECOLOGICAL PHASES OF THE WHITE SUCKER IN JACK LAKE, ONTARIO,
Trent Univ., Peterborough (Ontario). Dept. of Biology.
B. Corbett, and P. M. Powles.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 308-313, March, 1983. 5 Fig, 3 Tab, 23 Ref.

Descriptors: *Sucker, *Spawning, Growth, Water temperature, Drift, Fish food, Hatching, Marinas, Channels, Jack Lake, Ontario.

In 1979, peak spawning of white suckers Catostomus commersoni occurred on April 20-21 (9-15 C and 17-22 C) at night over fast riffle in a tributary of Jack Lake. Eggs hatched in 16 days and drift occurred in 27-29 days; maximum drift occurred between 2100 and 0100 hours. An estimated 11,800 postlarvae drifted to the nursery, a new boat channel and marina area in Jack Lake. Postlarvae phase 1 (terminal mouth, 15-17 mm total length, TL) and phase 2 (subterminal mouth, 18-34 mm TL) were spent in the nursery. At 28 C (midsummer), phase-3 fish (35-84 mm TL) moved out to the lake shores near the nursery, and later dispersed into the lake basin. Growth of white suckers was slower in phase 1 than in phase 2, and diets differed slightly between these intervals. Phase-3 fish did not grow significantly faster than phase-2 fish in spite of their more diverse diet. The cooler lake habitat may account for a lack of surge in the growth rate of phase-3 fish, or diversity of food may be an indica-

tion of food scarcity away from the nutrient-rich nursery area. (Author's abstract)

IDENTIFICATION OF CATOSTOMID LARVAE IN PYRAMID LAKE AND THE TRUCKEE RIVER, NEVADA,
Colorado State Univ., Fort Collins. Larval Fish Lab.
D. E. Snyder.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 333-348, March, 1983. 10 Fig, 5 Tab, 37 Ref.

Descriptors: *Spawning, *Larvae, *Suckers, Distribution, Pyramid Lake, Truckee River, Nevada.

As adults, mountain suckers Catostomus platyrhynchus inhabit the Truckee River, Tahoe suckers Catostomus tahoensis both the river and Pyramid Lake, and the endangered cui-ui Chasmistes cujus the lake only, except during the spawning season. All spawn in the river and under certain conditions the latter two species also spawn in the lake. The development of adequate water and fishery management techniques to insure the survival of the endangered cui-ui requires knowledge of the fish's reproductive and early life history requirements. Diagnostic characters useful in identifying most larvae and early juveniles include differences in pigmentation, size at the onset of specific developmental events, and gut and mouth morphologies. Fin-ray counts, myomere counts, and morphometric characters are very similar and of little diagnostic value. Based on these criteria, larvae of the cui-ui were identified in Pyramid Lake collections, and larvae and juveniles of the mountain and Tahoe suckers were identified in both lake and river collections. All the cui-ui were taken in the lake substantial distances from the Truckee River delta, and may represent natural spawning in Pyramid Lake during 1974 and 1975. The presence of mountain suckers in Pyramid Lake had not been previously documented. (Moore-IVI)

MICROHABITATS CHOSEN BY BROWN TROUT FOR FEEDING AND SPAWNING IN RIVERS,
C. S. Shirvell, and R. G. Dungey.
Transactions of the American Fisheries Society, Vol. 112, No. 3, p 355-367, May, 1983, 5 Fig, 7 Tab, 31 Ref.

Descriptors: *Trout, *Spawning, *Feeding, Aquatic habitats, Water depth, Velocity, Fish population, Population dynamics, Substrates, Rivers, New Zealand.

This study's objective was to quantify the water depth, water velocity, and substrate used by adult brown trout Salmo trutta for feeding and spawning in rivers. General hypotheses were: (1) brown trout prefer specific magnitudes of environmental variables and occupy positions through choice; (2) the preferred value of any variable for a particular activity is the same in all rivers; (3) brown trout prefer different values of the same variable for different activities. Surface observation was used to locate 140 feeding and 140 spawning positions used by brown trout in both isolated and sympatric (with rainbow trout Salmo gairdneri) populations in six diverse rivers in New Zealand. Brown trout (mean fork length 42 cm) preferred a mean depth of 65.0 cm and a mean velocity of 26.7 cm/sec at the position occupied by the fish for feeding, but for spawning they preferred a mean depth of 31.7 cm, a mean velocity of 39.4 cm/sec, and a mean substrate size of 14.0 mm. Analysis of variance showed brown trout preferred the same velocity for the same activity in all rivers and years regardless of whether they were from allopatric or sympatric populations, but microhabitats used for feeding and spawning were significantly different. Velocity appeared to be the most important factor determining position choice but ranking of factors may vary with the type of activity. Brown trout chose positions with optimum combinations of depth and velocity instead of positions with more preferred values of either factor alone. Population size maybe limited by the amount of the least abundant activity-specific microhabitat. (Author's abstract)

COMMUNITY ANALYSIS IN FISHERY MANAGEMENT: AN APPLICATION WITH NORTHERN WISCONSIN LAKES,
Wisconsin Univ.-Madison. Center for Limnology.
W. M. Tonn, J. J. Magnuson, and A. M. Forbes.
Transactions of the American Fisheries Society, Vol. 112, No. 3, p 368-377, May, 1983. 5 Fig, 2 Tab, 43 Ref. DEB 79-12337, F-83-R.

Descriptors: *Fisheries, *Lakes, Aquatic habitats, Management, Biological communities, Multivariate analysis, Fish, Water depth, Hydrogen ion concentration, Conductivity, Watersheds, Lake area, Wisconsin.

Decisions in fishery management usually are made on a species-by-species and site-by-site basis because most information about fishes has been collected and organized in this way. A comparative, community-level approach can contribute to the development of management strategies for large sets of lakes and fish assemblages. An approach similar in concept to lake classification uses a technique of multivariate community analysis (ordination, classification, multiple discriminant analysis). This approach can reveal patterns among fish assemblages and relate them to the lakes' habitat characteristics. An application of the approach is illustrated by a published study on fish assemblages of 18 small lakes in northern Wisconsin. Two discrete assemblage types were distinguished and the factors believed to be responsible for their maintenance were identified. With relationships derived from those 18 lakes, predictions of the assemblage types of 11 additional lakes are made from only five habitat characteristics obtained from the literature. The five environmental variables include lake area, maximum depth, pH, watershed size, and conductivity. Analyses showed these predictions to be largely successful. It is suggested that multivariate community analysis contributes to an ability to understand, predict, and manage fish assemblages. (Moore-IVI)

CHANGES IN FISH POPULATIONS OVER AN 80-YEAR PERIOD: BIG PINE LAKE, WISCONSIN,
Wisconsin Univ.-Madison. Center for Limnology.
P. D. Inskip, and J. J. Magnuson.
Transactions of the American Fisheries Society, Vol. 112, No. 3, p 378-389, May, 1983. 5 Fig, 4 Tab, 37 Ref.

Descriptors: *Fish populations, Muskellunge, Walleye, Pike, Bass, Population dynamics, Lake fisheries, Sport fishing, Temperature, Big Pine Lake, Wisconsin.

From 1897 to 1977, landowners recorded sport catches for Big Pine Lake, a 256 hectare lake in northern Wisconsin that has experienced light fishing pressure. The species composition of the catch remained fairly stable for 40 years, from 1897 to 1940, with muskellunge Esox masquinongry, walleye Stizostedion vitreum vitreum, and black bass (Micropterus spp.) all accounting for substantial fractions of the total. Northern pike Esox lucius were first recorded in 1946, apparently having entered after an outlet dam washed out in 1944. Subsequent increases in the proportion of northern pike coincided with declining percentages of muskellunge. By the 1950s, the relative abundance of walleye declined, ultimately almost to zero, while the percentage of bass more than doubled. This change began during the warmest decade on record. By 1977, the walleye population had rebounded, bass had declined to pre-1940 levels, northern pike were abundant, and muskellunge were relatively scarce. Long-term changes in summer temperatures and colonization by northern pike appear to have been important factors causing changes in species composition. Effects of human exploitation have been slight. Although the species composition changed dramatically over the 80 years, the only sustained change has been the substitution of northern pike for muskellunge. (Author's abstract)

COMMUNITY STRUCTURE DYNAMICS EPILITHIC AND EPIPHYTIC DIATOMS MISSISSIPPI STREAM,
Mississippi State Univ., Mississippi State. Dep Biological Sciences.
R. O'Quinn, and M. J. Sullivan.
Journal of Phycology, Vol. 19, No. 2, p 123 June, 1983. 2 Fig, 3 Tab, 25 Ref. A-133-M

Descriptors: *Diatoms, *Aquatic habitats, Bio cal communities, Stream biota, Epilimnion, E ton, Species diversity, Light intensity, Substr Seasonal variation, Mississippi.

Epilithic and epiphytic diatoms were colle monthly from 18 June 1979 through 19 May from both shaded and unshaded sites of Ses Creek, a shallow, oligotrophic and strongly line stream in northeastern Mississippi. The d nant macroalgae were filamentous green alga longing to the nonmucilage genera dophora and Rhizoclonium. Ninety taxa identified, with Navicula minima Grun. and N chia dissipata (Kutz) Grun. accounting for 50 all valves counted. Other important taxa were vicula menisculus var. upsaliensis (Grun.) G N. cryptocephala var. veneta (Kutz) Rabh., nanthes minutissima Kutz. and Cymbela tu (Greg) Cl. With few exceptions, the more d nant taxa were equally abundant in the shaded unshaded sites and also in the epilithon and epi ton. Species diversity (H') and the number of in a sample in all four habitats showed an iden pattern, being lowest in winter and highest in No one pair of habitats were more struct similar than any other pair when compared similarity index (SIMI). Apparently, differenc light intensity and substrate type had little effe diatom distribution in Sessums Creek and it concluded that the locality sampled support single, nearly homogeneous diatom commu (Author's abstract)

Cyprinid fishes were collected from the Oklah drainage of the Illinois River in all seasons of and 1979. The Illinois River and its tributa drain the Ozark Plateau and the Boston Moun and support an Ozarkian Fish fauna. Specie cluded in this analysis were Campostoma an lum, Nocomis asper, Notropis boops, N. nub N. pilsbryi, N. rubellus, N. whipplei, Pimeph notatus, Phoxinus erythrogaster and Semo atromaculatus. Fishes were collected and 17 e ronmental variables measured from each o localities sampled in every season. Species dist tions were characterized in reference to each able as follows: the value of a variable at location was weighted by the number of ind uals of a species present, and the mean of t weighted values was taken as that species' ferred state for that variable. Principal compon analysis, with rotation of the component solu to simple structure, was used to elucidate the tionships among variables in terms of species d butions. In most seasons, components relate species preferences for upstream vs. downstr locations, different foods, and slow- vs. fast-w habitats. For most species, differences in ha preference between seasons were related to br ing (in the spring) and to preference for wa

ations during the rest of the year. (Author's tract)

LOROPHYLL A AND ADENOSINE TRI-OSPHATE LEVELS IN ANTARCTIC AND MPERATE LAKE SEDIMENTS,
ginia Polytechnic Inst. and State Univ., Blacks-g. Dept. of Biology.
M. Simmons, Jr., R. A. Wharton, Jr., B. C. ker, and D. Andersen.
rnal of Microbial Ecology, Vol. 9, No. 2, p 123-, July, 1983. 2 Fig, 7 Tab, 50 Ref. 76-23996, 79-05.

scriptors: *Adenosine triphosphate, *Chloro-ll a, *Lake sediments, Trophic level, Antarctic, nperate zone, Benthic algae, Microorganisms, tic state.

alysis of adenosine triphosphate (ATP) from ficial sediment layers in two antarctic lakes and temperate lakes showed a high degree of ilarity in spite of differences between trophic e, mictic state, or geographic location. Adeno- triphosphate was found at all levels sampled in perate lake sediment cores but occasionally present only in surficial layers of antarctic es. Surficial sediment layers from antarctic es contained high chlorophyll a (Chl a) levels to the extensive benthic algal mats which ur there. In some antarctic cores, Chl a was ectable in deep, old mat layers, whereas Chl a not found in any of the temperate lake cores. arctic lake sediments appear to be unique envi-ments where Chl a molecules can remain intact long periods of time due to low light, tempera-, and microbial activity. As such, these lakes important natural laboratories where a long ory of microbial interations can be studied nout metazoan perturbation effects. Although e was much variability in concentration of Chl d ATP between samples, there appears to be relationship between Chl a or ATP levels to tic or trophic states of the lakes. These data gest that sediment microbial communities may independent of environmental and biological perties of the overlying water masses. (Author's ract)

ISYMMETRIC VERTICAL CIRCULATION A STRATIFIED RESERVOIR,
hnical Univ. of Szczecin (Poland). Inst. of er Engineering.
Meyer.
rnal of Hydraulic Research, Vol. 21, No. 2, p 151, 1983. 10 Fig, 12 Ref.

criptors: *Water circulation, *Reservoirs, hemetical models, Density stratification, lies, Selective withdrawal.

athematical model of vertical circulation in a sity-stratified reservoir is presented for the case xially symmetric flow, particularly for the flow erated by selective withdrawal. The method olves conditions such as location of intake, tified flow parameters, and various eddy vis-ties in the vertical and horizontal directions. analytical solution of the problem is given in is of Fourier series. The solution covers two ial cases, gradually and continuously converg-channels, for which a mechanism of formation he surface circulation region is described. The hod takes account of additional horizontal den- changes in a reservoir. Those appear to have ificant influence upon the extent of the region irculation. The characteristic features of the pattern are circulation regions at the surface bottom. Within those regions there exist inter-closed eddies which cause vertical circulation vater in a density-stratified reservoir. A source equentially created internal eddies is the corner veen the free water surface and the intake er. (Moore-IVI)

E AND BE IN THE MAURICE RIVER-ION LAKE SYSTEM OF SOUTHERN NEW SEY,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Chemistry.
L. Lundberg, T. Ticich, G. F. Herzog, T. Hughes, and G. Ashley.
Journal of Geophysical Research, Vol. 88, No. C7, p 4498-4504, May 20, 1983. 3 Fig, 1 Tab, 22 Ref.

Descriptors: *Beryllium, *Isotope studies, Lakes, Silicates, Organic matter, Isotopic tracers, Maurice River, Union Lake, New Jersey.

The Be10 and Be contents of 22 samples taken from seven locations in the Maurice River-Union Lake system of southern New Jersey are reported. Bulk Be10 contents range 0.05 to 2.7 dpm/kg and Be from <0.1 to 2 ppm. Silicate minerals separated from Union Lake sediments appear to have a constant surface concentration of about 500,000 atoms Be10/sq cm. Organic material is greatly enriched in Be: hand-picked samples contain over 10 dpm/kg of Be10 and 5 ppm of Be. The deposition rate of Be10 in Union Lake is about 1 atoms/sq cm s. (Author's abstract)

INTERBIOME COMPARISON OF STREAM ECOSYSTEM DYNAMICS,
Idaho State Univ., Pocatello. Dept. of Biology.
G. W. Minshall, R. C. Petersen, K. W. Cummins, T. L. Bott, and J. R. Sedell.
Ecological Monographs, Vol. 53, No. 1, p 1-25, 1983. 19 Fig, 10 Tab, 63 Ref.

Descriptors: *Ecosystems, *Streams, *Organic matter, Stream order, Productivity, Watersheds, Headwaters, Aquatic environment, Turnover time, Velocity, Decomposition, Leaf pack, Aquatic biota.

Studies were conducted in four distinct geographic areas (biomes/sites) in northern United States to examine changes in key ecosystems parameters; benthic organic matter (BOM), transported organic matter (TOM), community production and respiration, leaf pack decomposition, and functional feeding-group composition along gradients of increasing stream size. Four stations ranging from headwaters (1st or 2nd order) to midsized rivers (5th to 7th order) were examined at each site using comparable methods. The results for each parameter are presented and discussed in each site using comparable methods. The results for each parameter are presented and discussed in light of the River Continuum Concept of Vannote et al. (1980). The postulated gradual change in a stream ecosystem's structure and function is supported by this study. However, regional and local deviations occur as a result of variations in the influence of: (1) watershed climate and geology, (2) riparian conditions, (3) tributaries, and (4) location-specific lithology and geomorphology. In particular, the continuum framework must be visualized as a sliding scale which is shifted upstream or downstream depending on macroenvironmental forces (1 and 2) or reset following the application of more localized 'micro'-environmental influences (3 and 4). Analysis of interactions between BOM and TOM permitted evaluation of stream retentiveness for organic matter. Headwaters generally were most retentive and downstream reaches the least. Estimates of organic matter turnover times ranged between 0.2 and 14 yr, and commonly were 1-4 yr. Both turnover times and distances were determined primarily by the interaction between current velocity and stream retention. Biological processes played a secondary role. However, the streams varied considerably in their spiraling of organic matter due to differences in the interplay between retentiveness and biological activity. Differences in the relative importance of retention mechanisms along the continuum suggests that headwater stream ecosystems may be functionally more stable, at least to physical disturbances, than are their intermediate river counterparts. POPULATION ECOLOGY OF NITRIFIERS IN A STREAM RECEIVING GEOTHERMAL INPUTS OF AMMONIUM,
Ministry of Works and Development, Hamilton (New Zealand). Water and Soil Science Centre.
A. B. Cooper.
Applied and Environmental Microbiology, Vol. 45, No. 4, p 1170-1177, April, 1983. 3 Fig, 4 Tab, 19 Ref.

Descriptors: *Nitrification, *Bacteria, *Ammonium, Geothermal water, Nitrates, Sediments, Oxygenation, Nitrosospira, Nitrosomomas.

The distribution, activity, and generic diversity of nitrifying bacteria in a stream receiving geothermal inputs of ammonium were studied. The high estimated rates of benthic nitrate flux (33 to 75 mg of N/sq m/h) were a result of the activity of nitrifiers located in the sediment. Nitrifying potentials and ammonium oxidizer most probable numbers in the sediments were at least one order of magnitude higher than those in the waters. Nitrifiers in the oxygenated surface (0 to 2 cm) sediments were limited by suboptimal temperature, pH, and substrate level. Nitrifiers in deep (nonsurface) oxygenated sediments did not contribute significantly to the changes measured in the levels of inorganic nitrogen species in the overlying waters and presumably derived their ammonium supply from ammonification within the sediment. Ammonium-oxidizing isolates obtained by a most probable number nonenrichment procedure were species of either Nitrosospira or Nitrosomonas, whereas all those obtained by an enrichment procedure (i.e., selective culture) were Nitrosomonas spp. The efficiency of the most-probable-number method for enumerating ammonium oxidizers was calculated to be between 0.05 and 2.0%, suggesting that measurements of nitrifying potentials provide a better estimate of nitrifying populations. METHANOGENESIS FROM METHANOL AND METHYLAMINES AND ACETOGENESIS FROM HYDROGEN AND CARBON DIOXIDE IN THE SEDIMENTS OF A EUTROPHIC LAKE,
Michigan State Univ., Hickory Corners. W.K. Kellogg Biological Station.
D. R. Lovley, and M. J. Klug.
Applied and Environmental Microbiology, Vol. 45, No. 4, p 1310-1315, April, 1983. 1 Fig, 4 Tab, 21 Ref.

Descriptors: *Metabolism, *Methanogenesis, *Acetogenesis, *Sediments, Eutrophic lakes, Methanol, Methylamines, Carbon dioxide, Hydrogen, Acetates, Wintergreen Lake, Michigan.

Carbon-14 tracer techniques were used to examine the metabolism of methanol and methylamines and acetogenesis from hydrogen and carbon dioxide in sediments from the profundal and littoral zones of eutrophic Wintergreen Lake, Michigan. Methanogens were primarily responsible for the metabolism of methanol, monomethylamine, and trimethylamine and maintained the pool size of these substrates below 10 micro M in both sediment types. Methanol and methylamines were the precursors for less than 5 and 1%, respectively, of the total methane produced. Methanol and methylamines continued to be metabolized to methane when the sulfate concentration in the sediment was increased to 20mM. Less than 2% of the total acetate production was derived from carbon dioxide reduction. Hydrogen consumption by hydrogen-oxidizing acetogens was 5% or less of the total hydrogen uptake by acetogens and methanogens. These results, in conjunction with previous studies, emphasize that acetate and hydrogen are the major methane precursors and that methanogens are the predominant hydrogen consumers in the sediments of this eutrophic lake. RADIOASSAY FOR HYDROGENASE ACTIVITY IN VIABLE CELLS AND DOCUMENTATION OF AEROBIC HYDROGEN-CONSUMING BACTERIA LIVING IN EXTREME ENVIRONMENTS,
Wisconsin Univ.-Madison. Dept. of Bacteriology.
B. Schink, F. S. Lupton, and J. G. Zeikus.

Applied and Environmental Microbiology, Vol. 45, No. 5, p 1491-1500, May, 1983. 10 Fig, 2 Tab, 32 Ref.

Descriptors: *Bacteria, *Hydrogenase, *Hydrogen metabolism, *Isotopic tracers, Saline water, Acid water, Thermal water, Aerobic conditions, Desulfovibrio, Clostridium, Methanosarcina, Natural waters, Extreme environments.

An isotopic tracer assay based on the hydrogenase-dependent formation of tritiated water from tritium gas was developed for in life analysis of microbial hydrogen transformation. This method allowed detection of bacterial hydrogen metabolism in pure cultures or in natural samples obtained from aquatic ecosystems. A differentiation between chemical-biological and aerobic-anaerobic hydrogen metabolism was established by variation of the experimental incubation temperature or by addition of selective inhibitors. Hydrogenase activity was shown to be proportional to the consumption or production of hydrogen by cultures of Desulfovibrio vulgaris, Clostridium pasteurianum, and Methanosarcina barkeri. The method was applied, in connection with measurements of free hydrogen and most-probable-number enumerations, in aerobic natural source waters to establish the activity and document the ecology of hydrogen-consuming bacteria in extreme acid, thermal, or saline environments. The utility of the assay is based in part on the ability to quantify bacterial hydrogen transformation at natural hydrogen partial pressures, without the use of artificial electron acceptors. HYDROGEN METABOLISM BY DECOMPOSING CYANOBACTERIAL AGGREGATES IN BIG SODA LAKE, NEVADA,
Geological Survey, Menlo Park, CA.
R. S. Oremland.
Applied and Environmental Microbiology, Vol. 45, No. 5, p 1519-1525, May, 1983. 5 Fig, 2 Tab, 26 Ref.

Descriptors: *Hydrogen metabolism, *Cyanobacteria, Cyanophyta, Bacteria, Nitrogen fixation, Fermentation, Metabolism, Decomposition, Anaerobic conditions, Big Soda Lake, Nevada.

Hydrogen production by incubated cyanobacterial epiphytes occurred only in the dark, was stimulated by C2H2, and was inhibited by O2. Addition of NO3(-) inhibited dark, anaerobic H2 production, whereas the addition of NH4(+) inhibited N2 fixation (C2H2 reduction) but not dark H2 production. Aerobically incubated cyanobacterial aggregates consumed H2, but light-incubated rates (3.6 micromol of H2/g/h) were statistically equivalent to dark uptake rates (4.8 micromol of H2/g/h), which were statistically equivalent to dark, anaerobic production rates (2.5 to 10 micromol of H2/g/h). Production rates of H2 were fourfold higher for aggregates in a more advanced stage of decomposition. Enrichment cultures of H2-producing fermentative bacteria were recovered from freshly harvested, H2-producing cyanobacterial aggregates. Hydrogen production in these cyanobacterial communities appears to be caused by the resident bacterial flora and not by the cyanobacteria. In situ areal estimates of dark H2 production by submerged epiphytes (6.8 micromol of H2/sq m/h) were much lower than rates of light-driven N2 fixation by the epiphytic cyanobacteria (310 micromol of C2H4/sq m/h). INITIAL EFFECTS OF THE MOUNT ST. HELENS ERUPTION ON NITROGEN CYCLE AND RELATED CHEMICAL PROCESSES IN RYAN LAKE,
Oregon State Univ., Corvallis. Dept. of Fisheries and Wildlife.
C. N. Dahm, J. A. Baross, A. K. Ward, M. D. Lilley, and J. R. Sedell.
Applied and Environmental Microbiology, Vol. 45, No. 5, p 1633-1645, May, 1983. 10 Fig, 6 Tab, 48 Ref.

Descriptors: *Mount St. Helens, *Volcanoes, *Nitrogen cycle, *Lakes, Nutrients, Cyanobacteria, Bacteria, Nutrient cycling, Phosphorus, Sulfur, Manganese, Iron, Organic carbon, Ryan Lake.

Ryan Lake, a 1.6-hectare basin lake near the periphery of the tree blowdown area in the blast zone 19 km north of Mount St. Helens, was studied from August to October 1980 to determine the microbial and chemical response of the lake to the eruption. Nutrient enrichment through the addition of fresh volcanic material and the organic debris from the surrounding conifer forest stimulated intense microbial activity. Concentrations of such nutrients as phosphorus, sulfur, manganese, iron, and dissolved organic carbon were markedly elevated. Nitrogen cycle activity was especially important to the lake ecosystem in regulating biogeochemical cycling owing to the limiting abundance of nitrogen compounds. Nitrogen fixation, both aerobic and anaerobic, was active from aerobic benthic and planktonic cyanobacteria with rates up to 210 nmol of N2/cm/h and 667 nmol of N2/l/h, respectively, and from anaerobic bacteria with rates reaching 220 nmol of N2/l/h. Nitrification was limited to the aerobic epilimnion and littoral zones where rates were 43 and 261 nmol of NO2/l/day, respectively. Potential denitrification rates were as high as 30 micromol of N2O/l/d in the anaerobic hypolimnion. Total bacterial numbers ranged from 1 x 10 to the 6th to 3 x 10 to the 8th power/ml with the number of viable sulfur-metal-oxidizing bacteria reaching 2,000,000/ml in the hypolimnion. A general scenario for the microbial cycling of nitrogen, carbon, sulfur, and metals is presented for volcanically impacted lakes. The important role of nitrogen as these lakes recover from the cataclysmic eruption and proceed back towards their prior status as oligotrophic alpine lakes is emphasized. (Author's abstract)

ESTIMATING BACTERIOPLANKTON PRODUCTION BY MEASURING (3H)THYMIDINE INCORPORATION IN A EUTROPHIC SWEDISH LAKE,
Uppsala Univ. (Sweden). Limnologiska Institutionen.
R. T. Bell, G. M. Ahlgren, and I. Ahlgren.
Applied and Environmental Microbiology, Vol. 45, No. 6, p 1709-1721, June, 1983. 2 Fig, 10 Tab, 77 Ref. Swedish National Science Research Council grant B-BU 3083-105.

Descriptors: *Bacteria, *Plankton, *Eutrophic lakes, *Thymidine, Primary productivity, Chrysophyta, Cyanophyta, Cyanobacteria, Biomass, Radioactive tracers, Carbon dioxide, Lake Norrviken, Sweden.

Bacterioplankton abundance, tritiated thymidine incorporation, carbon-14 labeled CO2 uptake in the dark, and fractionated primary production were measured on several occasions between June and August 1982 in eutrophic Lake Norrviken, Sweden. Bacterioplankton abundance and carbon biomass ranged from 0.5 x 10 to the 9th power to 2.4 x 10 to the 9th power cells/l and 7 to 47 micro g of C/l, respectively. The average bacterial cell volume was 0.185 cu micro m. Thymidine incorporation into cold-trichloroacetic acid-insoluble material ranged from 12 x 10 to the 12th power to 200 x 10 to the 12th power mol/l/h. Bacterial carbon production rates were estimated to be 0.2 to 7.1 micro g of C/l/h. Bacterial production estimates from thymidine incorporation and CO2 uptake in the dark agreed when activity was high but diverged when activity was low and when blue-green algae (cyanobacteria) dominated the phytoplankton. Size fractionation indicated negligible uptake of thymidine in the > 3 micro m fraction during a chrysophycean bloom in early June. More than 50% of the 3H activity was in the > 3 micro m fraction in late August; this phenomenon was most likely due to Microcystis spp., their as[s]ed bacteria, or both. Over 60% of the CO2 [u]in the dark was attributed to algae on each [sa]mpling occasion. Algal exudate was an imp[or]carbon source for planktonic bacteria. Ba[c]production was roughly 50% of primary pr[o]tion. (Moore-IVI)

COMPARISON OF DENITRIFICATION ESTIMATION TECHNIQUES IN A LA[R]SHALLOW LAKE,
Utah Water Research Lab., Logan.
J. Messer, and P. L. Brezonik.
Water Resources, Vol. 17, No. 6, p 631-640, [J]1983. 5 Fig, 5 Tab, 35 Ref.

Descriptors: *Denitrification, *Mass ba[l]*Bottle incubation, Model studies, Nitrates, C[ar]ic carbon, Suspended solids, Nitrogen input, [Flor]ida, Lake Okeechobee.

A comparison was made between various in[situ]tion techniques and a mass balance model fo[r] mating annual denitrification rates in Lake [O]chobee, Florida, a large, shallow lake. Incut[ation] techniques involving isolation of the sediment [with] nitrate and labile organic carbon sources tend[ed] produce low rate estimates, while diag[nostic] models based on nitrate profiles tended to pr[oduce] unrealistically high rate estimates. Each tech[nique] has inherent errors when used with frequ[ently] suspended sediments, but most incubation [tech]niques were in general agreement with mas[s bal]ance calculations. Denitrification rate esti[mates] range from 0.5 to 1.3 g N/sq m/yr, which r[epre]sents 9-23% of the average annual nitrogen i[nput] to the lake. (Author's abstract)

SURVEY OF STOCKING POLICIES FOR T[AIL]WATER TROUT FISHERIES IN THE SOU[THE]ERN UNITED STATES,
Fish and Wildlife Service, Bowling Green, [KY]. East Central Reservoir Investigations.
W. D. Swink.
Progressive Fish-Culturist, Vol. 45, No. 2, p [63]April, 1983. 3 Tab, 10 Ref.

Descriptors: *Trout, *Tailwater, *Fish stoc[king], Fisheries, Fingerlings, Fishing pressure.

A survey of the 16 southern states showed th[at] tailwaters in 13 states were stocked with tro[ut] 1980. Of the almost 3.7 million trout releas[ed] these waters, 81% were of catchable size and [79]were fingerlings (< 150mm). Tailwaters rec[eived] 32% of all trout stocked in the South; nearly [75]of the tailwater fish were rainbow trout (S[alm]gairdneri). A trend away from 'put-grow-and-[take]' fisheries toward 'put-and-take' fisheries was n[oted]. Limited creel data confirmed that fishing pre[ssure] in southern tailwaters was heavy, and that [>]90% of the trout stocked were recovered[by] anglers. (Author's abstract)

SENSITIVITY OF FLORIDA LAKES [TO] ACIDIC PRECIPITATION,
Florida Univ., Gainesville. School of Forest [Re]sources and Conservation.
D. E. Canfield, Jr.
Water Resources Research, Vol. 19, No. 3, p [834]839, June, 1983. 3 Fig, 4 Tab, 66 Ref. Dept. o[f the] Interior project 14-16-0009-79-064.

Descriptors: *Lakes, *Water chemistry, *Flo[rida], Hydrogen ion concentration, Alkalinity, Ca[lcium], Calcium, Hardness, Acid rain, Zooplankton, C[hlo]rophyll a, Lake fisheries.

To assess the potential vulnerability of Fl[orida] lakes to damage by acidic precipitation, data [from] a survey of 165 lakes located in the major ph[ysio]graphic and geologic regions of Florida were [used] to determine pH, total alkalinity, calcium hard[ness] and calcite saturation index values. Mean lak[e pH] ranged from 4.1 to 8.9. Mean total alkalinity [con]centrations ranged from 0 to 4100 ueq/l and r[anged]

ardness concentrations ranged from 20 to
/l. Total alkalinity averaged below 200
49% of the sampled lakes. Calcite satura-
values were greater than 4 in 36% of the
lakes. Based on these data, Florida has a
nber of lakes that are vulnerable to reduc-
pH and alkalinity by acidic precipitation.
chlorophyll a concentrations, zooplankton
e, and recent fisheries data, however,
at Florida lakes may not be as biological-
ve as the alkalinity and calcite saturation
ight suggest. Low phosphorus and nitro-
entrations are primarily responsible for
animal and plant populations in acidic
akes. Consequently, predictions of future
r trends based on current sensitivity indi-
ld be regarded with caution. (Author's

l, 1983. 3 Fig, 2 Tab, 20 Ref.

rs: *Moisture stress, *Defoliation, Mois-
ability, Ragwort, Rainfall, Weed control,
l control.

gwort plants were grown under different
regimes to assess the effect of summer
stress on their capacity to compensate for
n by larvae of the cinnabar moth. Three
of compensation capacity increased with
frequency of irrigation: the amount of
produced following defoliation, the
f nodes which produced this growth, and
er of flower heads (capitula) produced
defoliation. Thus moisture availability
ant compensation under these experimen-
ions. Compensation capacity was posi-
related with moisture availability in (a)
ns of populations at a high summer rain-
nd a low summer rainfall site and (b)
ns of populations during wet and dry
us moisture availability appeared to limit
pensation under natural as well as experi-
nditions. These results indicate that the
tial of the cinnabar moth as a biological
gent of tansy ragwort will be apparent in
n below average summer rainfall. In wet
introduction of additional biological con-
s should be considered. Investigation of
nces of abiotic conditions on the interac-
veen plants and their herbivores may be
in other studies concerned with predict-
utcome of this interaction. (Author's ab-

rs: *Snow depths, *Desert plants, *Vege-
il water, Shrubs, Snowpack, Wind, Melt-
mation, Utah.

t differences in average snow depths - for
es in each of four winters - occurred at
ions each in pure Atriplex confertifolia
toides lanata stands and an intermediate
cies stand. The average depth of snow
er the season that the snow lasted was
ly different between community types in
he four winters investigated. Average
th in the Ceratoides type was less than in
plex and the mixed type. The difference
y related to variations in stature of the vegetation which modify snow deposition, redistribution by wind, melting and sublimation. The difference in snow depth corresponded with greater soil moisture recharge under the taller vegetation for 1 year for which data were available. Occasional differential snowpack development in these adjacent communities may influence vegetation boundaries in this area. (Author's abstract)

SEDIMENTATION IN A LARGE LAKE: A REINTERPRETATION OF THE LATE PLEISTOCENE STRATIGRAPHY AT SCARBOROUGH BLUFFS, ONTARIO, CANADA,
Toronto Univ. (Ontario). Dept. of Geology.
C. H. Eyles, and N. Eyles.
Geology, Vol. 11, No. 3, p 146-152, March, 1983. 4 Fig, 37 Ref.

Descriptors: *Sedimentation, *Lakes, Glacial drift, Suspended sediments, Pleistocene, Canada.

A lithofacies code developed for diamicts emphasizes facies variability in the classic upper Pleistocene glaciogenic sequence at Scarborough Bluffs, Ontario, Canada. Lithological breaks along the bluffs are traditionally assigned to incursions of grounded ice margins and to interstadial lakes formed during ice retreat, during the Early and Middle Wisconsin. Detailed sedimentological logging through three diamict units (previously formalized as Sunnybrook, Seminary, and Meadowcliffe Tills) are intervening sandy lithofacies shows absence of glaciotectonic structures and diamicts associated with grounded glacier ice, traction-current activity during diamict accumulation, postdepositional resedimentation of diamicts into topographic lows accompanied by turbidite acitivity, a subaqueous deltaic origin for intervening sandy lithofacies, and loaded, transitional, and interbedded contacts between sand and diamict. The Scarborough Bluffs sequence may be the preserved bottom stratigraphy of a large lake. The bottom stratigraphy results from repeated basinward progradation of deltaic sandy lithofacies over glaciolacustrine diamicts deposted below floating ice, whether ice shelf, ramp, bergs, or lake ice. A facies model is presented by glaciolacustrine diamict deposition on the floors of enlarged Pleistocene lakes trapping substantial volumes of fine-grained suspended sediment. (Author's abstract)

REMODIFIED EINSTEIN PROCEDURE FOR SEDIMENT LOAD,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
H. W. Shen, and C. S. Hung.
Journal of Hydraulic Engineering, Vol. 109, No. 4, p 565-578, April, 1983. 5 Fig, 3 Tab, 7 Ref. ENG 7825054.

Descriptors: *Sediment transport, Suspended sediments, Flow, Sampling, River flow, Mathematical studies.

A procedure has been developed to calculate the total sediment transport rates from the flow and suspended sediment data collected from the sampled zone (by depth integrated sampler). This procedure is a modification of the well-known 'Modified Einstein Procedure.' The two major modifications are that (1) The z components in the Modified Einstein Procedure, based on the 0.7 power of the fall velocity, were replaced with a regression equation to be determined by actual field data; and (2) an optimization procedure with constraints was included to minimize the difference between the measured and calculated suspended sediment rates in the sampled zone. Using measured loads from large rivers, a comparison of suspended sediment loads calculated by the two methods indicates that this Remodified Einstein Procedure is superior to the Modified Einstein Procedure. Results from this study also indicate that sediment load in unsampled zone for larger rivers can exceed the measured sediment load in sampled zones. (Author's abstract)

THE HYDRAULICS OF RESERVOIR SEDIMENTATION,
Ecole Polytechnique Federale de Lausanne (Switzerland). Lab. d'Hydraulique.
W. H. Graf.
International Water Power and Dam Construction, Vol. 35, No. 4, p 45-52, April, 1983. 12 Fig, 52 Ref.

Descriptors: *Reservoirs, *Sedimentation, *Hydraulics, Deposition, Mathematical studies, Deltas, Erosion, River flow.

Various theoretical approaches to the problem of reservoir sedimentation are considered along with empirical predictions of delta formation. Predicting the deposition pattern can only be done for conditions which simplify the model. If the geometry of the channel-reservoir system, the change in roughness, the non-uniformity of the sediment, the hydrograph of the watercourse, and the reservoir operation are all taken into account, a very complex model is obtained. Deltas are formed if the flow of the river diminishes in velocity and the coarse fractions of incoming sediments are deposited. Bottom sediment is formed downstream from deltas, when the finer fractions are deposited. Important criteria are the evaluation of the water surface profile, which will change once deposition occurs, and evaluation of the bottom (bed) profile which will alter as deposition progresses. For hydraulic calculations it is necessary to satisfy the continuity of water flow, continuity of sediment transport, and conservation of momentum of waterflow. It is also necessary to use a relationship for sediment transport (bedload and/or suspended load), and a relationship for flow resistance. In the Lehigh approach, the backwater profile is obtained in a river-reservoir system, without the sediment transport being considered, and then the deposition of the bedload is determined in successive short reaches along the system. This approach is rather simple, yielding the growth and the advancement of the delta formation, resembling the ones observed in a real situation. In the Grenoble approach the evolution of the longitudinal profile of a river and the transport of sediments on the river bed are simulated. The HEC approach is similar in point of view of hydraulics to the other approaches. The concept of the approach is such that continuous updating can and is done. Other methods include dimensional analysis, load distribution relationships, and comprehensive surveys of the mathematical techniques of solving the water and sediment equation. (Baker-IVI)

DISSOLVED IONS, STABLE AND RADIOACTIVE ISOTOPES AND NOBLE GASES IN THERMAL WATERS OF SOUTH AFRICA,
University of the Witwatersrand, Johannesburg (South Africa). Nuclear Physics Research Unit.
E. Mazor, and B. Th. Verhagen.
Journal of Hydrology, Vol. 63, No. 3-4, p 315-329, June, 1983. 3 Fig, 6 Tab, 22 Ref.

Descriptors: *Thermal springs, *South Africa, *Water chemistry, Isotopes, Groundwater recharge, Tritium, Neon, Argon, Krypton, Xenon, Water temperature, Helium, Geochemistry.

Sixteen thermal springs of South Africa were studied. Chemically, two salinity groups were found; one group at 3-13 meq/l TDI (total dissolved ions) issuing in crystalline terrains, and a more saline group, 30-80 meq/l TDI, mostly associated with sedimentary rocks. Stable hydrogen and oxygen isotopic compositions indicate direct recharge by heavy rains and negligible intermixing with water from adjacent rivers. Tritium concentrations are generally low. In a few cases, tritium at the limit of

detection, combined with sub-recent C14, might indicate some admixture of recent water. Dissolved Ne, Ar, Kr and Xe occur at atmospheric isotopic composition and at concentrations indicating intake temperatures of 15-35 degrees C. These intake temperatures show a clear dependence of climatic and geographical factors. Some of the springs contain significant amounts of radiogenic helium, accompanied by radiogenic argon. The (He4/Ar40) radiogenic values are in the range of 1-7, indicating common rocks as the origin rather than concentrates (ores) of U and Th. Low helium values in some of the thermal springs are explained by large flows and short residence times. (Author's abstract)

ONE-DIMENSIONAL BED WAVE MOVEMENT IN LOWLAND RIVERS,
Department of Scientific and Industrial Research, Wellington (New Zealand). Applied Mathematics Div.
G. J. Weir.
Water Resources Research, Vol. 19, No. 3, p 627-631, June, 1983. 2 Tab, 22 Ref.

Descriptors: *Gravel, *Bed wave, *Sediment transport, Friction, Bed load, River beds, Wyoming, East Fork River.

Large quantities of gravel may translate down a river in the form of a bed wave. The central difficulties in formulating a one-dimensional gravel flow theory are the uncertainties in the transport laws for gravel and for water friction. Bed form translational speeds and the apparent changes in channel cross-sectional area are independent of water friction, but bed form evolution is water friction dependent. Recent measurements in the East Fork River, Wyoming, of annual gravel wave translation, annual bedload transport, and annual variations in riverbed cross-sectional area can be described to within a factor of 2 by using the Gradowczyk characteristic velocity for bed waves to describe gravel wave translation, the Engelund-Hansen formula for bedload transport, and a Du-Boyslike formula for changes in cross-sectional area. No free parameters are needed. (Moore-IVI)

VARIABILITY OF SEDIMENT REMOVAL IN A SEMIARID WATERSHED,
Arizona State Univ., Tempe. Dept. of Geography.
W. L. Graf.
Water Resources Research, Vol. 19, No. 3, p 643-652, June, 1983. 11 Fig, 1 Tab, 37 Ref. NSF grant EAR-7727698.

Descriptors: *Sediment erosion, *Semiarid lands, *Alluvium, Sediment transport, Channel morphology, Sediment storage, Stream order, Spatial distribution, Walnut Gulch Watershed, Arizona.

Field and documentary data from Walnut Gulch Watershed, an instrumented semiarid drainage basin of approximately 150 sq km (57 sq mi) in southeastern Arizona, show that 83% of the alluvium removed from the basin during a 15-year episode beginning about 1930 was excavated from the highest-order stream. The amount of alluvium removed in the erosion episode would have been equal to a covering of about 4 cm (1.6 in) over the entire basin. The rate of sediment removal during the erosion episode was 18 times greater than the rate of present channel sediment transport. Production of sediment from slopes and channel throughput as present rates are approximately equal, and refilling will not occur under present conditions. The channel forms left by the massive evacuation of sediment impose controls on the spatial distribution of tractive force and total stream power that make renewed storage of sediment likely in only a few restricted locations. Modern instrumented records of a decade or more provide an inadequate perspective on long-terms sediment movement. (Author's abstract)

PARTICULATE DYNAMICS, DISSOLVED AND TOTAL LOAD, IN TWO SMALL BASINS, NORTHERN PENNINES, UK,
Freshwater Biological Association, Ambleside (England).
P. A. Carling.
Hydrological Sciences Journal, Vol. 28, No. 3, p 355-375, September, 1983. 6 Fig, 5 Tab, 73 Ref.

Descriptors: *Suspended sediments, *Dissolved solids, Streamflow, Flashy streams, Cations, Precipitation, Storm runoff, Flow discharge, Hydrographs, Organic matter, Silt, Flood peak, Carl Beck, Great Eggleshope Beck, England.

Suspended sediment and dissolved load were measured in two upland piedmont gravel-bedded streams, Carl Beck and Great Eggleshope Beck, for one year. In addition, the input of major cations from precipitation and the cation content of springs within the basins were monitored. The dynamics of the suspended load through a series of storm flows were examined in relation to sediment supply and progressive exhaustion effects. In both Carl Beck and Great Eggleshope Beck suspended sediment concentration increased during storm periods with discharge. This increase was described by a second-order polynomial function with a tendency for the concentration to fall towards a constant suspended sediment concentration at baseflow of 3 mg/l. In each case, the load was an undercapacity load. The impact of sediment from collapsing stream banks, the variable timing of sediment concentration peaks in relation to the hydrograph peaks, and progressive sediment exhaustion effects reflect variable sediment supply. Nevertheless, in as much as storm discharge and concentration were correlated, hydraulic control of concentration level remained significant in these flashy streams. The organic concentration varied between 33 mg/l and less than 1 mg/l with an arithmetic mean of 4.8 mg/l. The concentration of the organic sediment increased as a power function of the total suspended sediment concentration. Most suspended inorganic material was coarse silt. Increases in mean grain size coincided with flood peaks when competancy was at a maximum and reflect the dominance of in-channel sediment sources. For Carl Beck, the total load for 1980 was calculated to be 135.38 t/sq km/year; for Great Eggleshope Beck, the total load was calculated to be 12.62 t/sq km/year. (Moore-IVI)

The potential for bioconcentration of naturally occurring radionuclides was investigated in yellow pond-lily and possible seasonal variations were also considered. Water, plant and lake sediment samples were collected from an area of high natural radioactivity in the Okanagan Highlands of south-central British Columbia. The water chemistry of the seven sample sites during both spring and summer showed increases in the dissolved U-nat content in the spring. There may have also been a slight variation in the concentration of Po-210, but it was not verified statistically. Both Ra-226 and Pb-210 stayed effectively below the limits of detection. Radionuclide concentrations in the sediments from each location did not differ significantly by season, though there were small changes, probably due to changes in the water table, surface run-off patterns and degree of saturation of the soil in the environs of the ore body. In autumn there was no correlation between the surface water pH and dissolved U-nat, but a higher negative correlation between surface water pH and sediment burden of U-nat existed. The data indicate that as the pH
aquatransport of U-nat decreases U-nat ap

AQUEOUS GEOCHEMISTRY AND THE CHANGEABLE CATION COMPOSITIO GLAUCONITE IN THE AQUIA AQU MARYLAND,

cal Survey, Towson, MD.
apelle, and L. L. Knobel.
Water, Vol. 21, No. 3, p 343-352, May-83, 6 Fig, 1 Tab, 15 Ref.

ors: *Water chemistry, *Aquifers, water movement, Cation exchange, Calagnesium, Potassium, Sodium, Glauconite, issolved oxygen, Aquia aquifer, Maryland.

ion composition of water in the Aquia of southern Maryland changes systematithe direction of ground-water flow. In the nt parts of the aquifer, calcium is the t cation in solution. Between 10 and 20 mi dient, calcium and magnesium are domiween 20 and 35 mi downgradient, magnel potassium are dominant, and, beyond 40 ngradient, sodium is the most abundant solution. The exchangeable cation comof glauconite in the Aquia aquifer changes ically in the direction of flow in a manner o the changes in water chemistry. These ions are interpreted as evidence that cation reactions are processes that simultaalter water composition and glauconite ion along the flowpath. Exchange paramand n for glauconite in the Aquia aquifer ermined, and the exchange parameters for ction were tested by an indirect method. tios of exchangeable cations on glauconite culated from water chemistry data using ed K' and n values. The sum of exchangans on glauconite samples is significantly the outcrop area than downgradient. Corng to this, the concentration of dissolved l dissolved oxygen in Aquia water is high outcrop area and decreases downgradient. ern suggests that incongruent dissolution nite is an additional process that modifies e composition near the outcrop area but is rtant downgradient. IGATION OF THE FOLIN-CIOCAL-HENOL REAGENT FOR THE DETER-ON OF POLYPHENOLIC SUB-S IN NATURAL WATERS,
er Biological Association, Ambleside).

esources, Vol. 17, No. 5, p 511-525, May, ig, 10 Tab, 43 Ref.

Descriptors: *Phenols, *Water analysis, *Natural waters, Tannin, Tannic acid, Fulvic acid, Tyrosine, Organic compounds, Iron hydroxide.

The methodology associated with the Folin-Ciocalteau phenol reagent was investigated and the performance characteristics of a method using sodium carbonate as the supporting medium were determined. Calibration curves using phenol, tannic acid, or L-tyrosine were linear up to at least 1000 micrograms/l. The limit of detection was 6 micrograms phenol/l and the relative standard deviation at 100 micrograms phenol/l was 5.2% and at 1000 micrograms phenol/l was 4.1%. The absorbances obtained with equal amounts of a range of potential standards showed variations when compared with that of phenol: phenol (100%). L-tyrosine (62%), oak gall tannin (58%), tannic acid (48%), chestnut tannin (26%), oak tannin (24%), fulvic acid (5%). The method was applicable to a wide range of monohydric and polyhydric phenolic substances and interferences from inorganic and non-phenolic organic compounds were examined. Interference would be expected above 30 micrograms S(2-)/l, 300 micrograms Mn(II)/l, or 400 micrograms SO3(2-)/l. Concentrations of iron > 2 mg/l as Fe(II) or Fe(III) formed the insoluble iron (III) hydroxide which increased the absorbance, but centrifugation could be used to remove this source of interference. Other potential sources of interference (e.g. reducing agents and certain metabolic products) would be expected to have a negligible effect in unpolluted waters. Methods using diazotized sulfanilic acid or 4-aminoantipyrine (4-AAP) were found to be inferior when applied to natural water samples. (Author's abstract)

CALCITE SUPERSATURATION AND PRECIPITATION KINETICS IN THE LOWER COLORADO RIVER, ALL-AMERICAN CANAL AND EAST HIGHLINE CANAL,
Agricultural Research Service, Riverside, CA. Salinity Lab.
D. L. Suarez.
Water Resources Research, Vol. 19, No. 3, p 653-661, June, 1983. 8 Fig, 20 Ref.

Descriptors: *Calcite, *Supersaturation, *Colorado River, Chemical precipitation, Return flows, Saline water, Calcium carbonate, Residence time, Suspended load, Algae, Seasonal variation, Diurnal distribution, Chemical kinetics, All-American Canal, East Highline Canal.

In situ pH determinations and analysis of major ions in solution indicated that the lower Colorado River is supersaturated with respect to calcite throughout the entire daily cycle, in both winter and summer. Although the ion activity product was 4 to 6 times greater than the calcite solubility product, there was no detectable precipitation. Chemical analyses of water samples taken along 350 km of the river and canals from Parker Dam to the Salton Sea also revealed no evidence of calcium carbonate precipitation despite the inflow of saline and highly supersaturated irrigation return flows. Laboratory kinetic studies indicated that calcite crystal growth rates with Colorado River water are about 30% of the rate for pure Ca-HCO3 waters and about 70% of that for synethic Colorado River water. Calcite precipitation by crystal growth in the river is limited by the combination of short residence times and unavailability of reactive calcite. Critical supersaturation levels necessary for heterogeneous nucleation do not occur; a high suspended load limits algal photosynthesis and thus prevents large decreases in daytime H2CO3 levels. (Author's abstract)

KINETIC ANALYSIS OF STRONTIUM AND POTASSIUM SORPTION ONTO SANDS AND GRAVELS IN A NATURAL CHANNEL,
Geological Survey, Menlo Park, CA.
K. E. Bencala, A. P. Jackman, V. C. Kennedy, R. J. Avanzino, and G. W. Zellweger.
Water Resources Research, Vol. 19, No. 3, p 725-731, June, 1983. 9 Fig, 2 Tab, 19 Ref.

Descriptors: *Sorption, *Mass transfer, *Strontium, *Kinetics, *Potassium, Sand, Gravel, Mathematical models, Particle size, Mountain streams, Uvas Creek, California.

A kinetic, first-order mass transfer model was used to describe the sorption of strontium onto sand-and gravel-sized streambed sediments. Rate parameters, empirically determined for strontium, allowed for the prediction of potassium sorption with moderate success. The model parameters varied significantly with particle size. The sorption data were collected during an experimental injection of several elements into Uvas Creek, a small mountain pool-and-riffle stream on the Eastern slope of the Santa Cruz Mountains in California. The processes simulated are expected to also occur in much larger high-gradient streams. The sorption process onto sand-and gravel-sized sediment was relatively slow compared to changes in the dissolved concentrations. Although the model is empirical, qualitative interpretations can be given to the physical significance of the model and their size-dependent trends. (Moore-IVI)

SIMULATION OF SOLUTE TRANSPORT IN A MOUNTAIN POOL-AND-RIFFLE STREAM WITH A KINETIC MASS TRANSFER MODEL FOR SORPTION,
Geological Survey, Menlo Park, CA.
K. E. Bencala.
Water Resources Research, Vol. 19, No. 3, p 732-738, June, 1983. 7 Fig, 2 Tab, 21 Ref.

Descriptors: *Solute transport, *Mass transfer, *Sorption, Simulation, Streambeds, Mathematical models, Strontium, Kinetics, Pools, Riffles, Mountain streams, Hydrodynamics.

In natural channels there are often long periods of low flow during which solutes have repeated opportunity for contact with relatively immobile bed materials. Such conditions can exist in very small pool-and-riffle mountain streams. If a solute can sorb onto bed materials, then both hydrodynamics and chemical processes control solute transport. A simulation of these processes is presented for a carefully controlled and intensively monitored strontium injection experiment. The numerical model couples nonreactive, transient storage with a kinetic mass transport model for sorption. The results are compared to both in-stream and on-sediment strontium measurements. In mountain streams the stream hydrology is complex and is governed by a wide variety of time and distance scales. The present simulations assist in interpreting the relative roles of hydrologic and sorptive kinetic processes, and indicate the practical limits of our process and parameter knowledge. The simulations are relatively insensitive to the details of the kinetic mechanisms and to the spatial variability of the stream parameters. (Author's abstract)

SUPPLY-BASED MODELS OF SUSPENDED SEDIMENT TRANSPORT IN STREAMS,
Oregon State Univ., Corvallis. Dept. of Forest Engineering.
J. VanSickle, and R. L. Beschta.
Water Resources Research, Vol. 19, No. 3, p 768-778, June, 1983. 9 Fig, 1 Tab, 29 Ref.

Descriptors: *Sediment transport, *Suspended sediments, *Mathematical models, Sediment storage, Streamflow, Storm runoff, Reservoir releases, Flynn Creek Watershed, Oregon, Electric Lake Reservoir, Utah.

Most of the uncertainty in empirical streamflow-sediment relationships can be attributed to changing supplies. The transport model utilizes a power function which was augmented with a variable S representing sediment storage in the channel system. The resulting supply-based model was calibrated to concentration and streamflow time series data from four storm events in Flynn Creek watershed, a small forested watershed in coastal Oregon. The model was calibrated to data from a controlled release from Electric Lake Reservoir in Utah, during which streamflow was held constant for an extended period. The supply-based model

followed observed concentration time series more accurately than did a transport model based on S alone. Performance of the supply-based model was further enhanced by distributing sediment supplies S among several compartments which were accessed at different levels of stream discharge. Both the single-compartment and distributed models demonstrate that a knowledge of sediment supplies can improve predictions of suspended sediment concentrations during storm runoff. (Moore-IVI)

SEASONAL DIVERSITY, ABUNDANCE, AND DISTRIBUTION OF ICHTHYOPLANKTON IN TAMIAHUA LAGOON, WESTERN GULF OF MEXICO,
Universidad Nacional Autonoma de Mexico, Mexico City. Centro de Ciencias del Mar y Limnologia.
C. Flores-Coto, F. Barba-Torres, and J. Sanchez-Robles.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 247-256, March, 1983. 5 Fig, 2 Tab, 31 Ref.

Descriptors: *Plankton, *Lagoons, *Fish, Larvae, Salinity, Water temperature, Seasonal variation, Species diversity, Tamiahua Lagoon, Mexico.

The ichthyoplanktonic community of Tamiahua Lagoon, Veracruz, Mexico, was studied throughout an annual cycle. Major concentrations of larvae occurred in the central portion of the lagoon, occasionally along the channels, but never at the inlets. The cycle of larva abundance was correlated with cycles of salinity and temperature. In spite of the greater number of species then, the spring and summer periods had low species diversity and evenness, due to the marked domination by larvae of Anchoa mitchilli. The number of larval fish species and individuals entering the lagoon from the adjacent offshore waters was minimal. The greatest portion of species diversity is generated within the lagoon itself. The community structure identified corresponds to the physically controlled type, as indicated by the poor diversity values obtained. (Author's abstract)

SPATIAL DISTRIBUTION PATTERNS OF PLANKTONIC FISH EGGS IN LOWER MOBILE BAY, ALABAMA,
University of South Alabama, Mobile. Dept. of Biology.
R. D. Marley.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 257-266, March, 1983. 8 Fig, 1 Tab, 26 Ref.

Descriptors: *Estuaries, *Fish eggs, *Spatial distribution, Salinity, River discharge, Spawning, Water circulation, Mobile Bay, Alabama.

A 12-month survey of planktonic fish eggs in lower Mobile Bay yielded 110 samples containing over 105 eggs. Fourteen taxa were represented, of which eight were abundant enough for analysis. By normal and inverse schemes of numerical classification, two distinct assemblages (station groups), coastal and estuarine, were found. The coastal assemblage was influenced by high-salinity tidal intrusions, whereas the estuarine assemblage was influenced by low-salinity estuarine water and river discharge. The spawning location of adult fish, circulation patterns, and salinity gradients (due to river discharge) were responsible for delineating the two assemblages. There also were two species associations (species groups). Eggs of Anchoa mitchilli, Sciaenidae, and Symphurus sp. were ubiquitous in both the estuarine and coastal assemblages. The eggs of Harengula jaguana, Anchoa hepsetus, Anchoa sp., Chloroscombrus chrysurus, and Trinectes maculatus were found predominantly in the coastal assemblage. Month-to-month differences in the spatial distribution of eggs reflected the magnitude of river discharge into the estuary. All fish eggs were confined to bottom waters during high river discharge, but were about equally divided between surface and bottom waters when river discharge was low. (Author's abstract)

THE EFFECT OF NITROGEN FERTILIZATION ON THE PRODUCTION OF HALOPHYTES IN AN INLAND SALT MARSH,
Ohio Univ., Athens. Dept. of Botany.
D. G. Loveland, and I. A. Ungar.
American Midland Naturalist, Vol. 109, No. 2, p 346-354, April, 1983. 5 Fig, 2 Tab, 31 Ref. DEB 79-27236.

Descriptors: *Salt marshes, *Nitrogen, *Marsh plants, Halophytes, Productivity, Nutrients, Fertilization, Ohio.

The effect of nitrogen fertilization on plant production, soil and plant nitrogen content, and species distribution in an Ohio salt marsh was analyzed. Seasonal measurements indicate that the three dominant species attained maximal production at different times during the growing season. Production of Salicornia europaea increased with nitrogen fertilization and it appears that reduced soil nitrogen concentrations may be responsible for the different growth forms of S. europaea found in this marsh. Shoot nitrogen concentrations of S. europaea were inversely related to the growth response to fertilization. High tissue nitrogen concentrations in Hordeum jubatum and Atriplex triangularis suggest that some factor other than nitrogen is limiting to these species. (Author's abstract)

EFFECTS OF PERMANENT FLOODING ON CAREX-EQUISETUM WETLANDS IN NORTHERN SWEDEN,
Sveriges Lantbruksuniversitet, Umea. Dept. of Wildlife Ecology.
K. Sjoberg, and K. Danell.
Aquatic Botany, Vol. 15, No. 3, p 275-286, March, 1983. 3 Fig, 4 Tab, 33 Ref.

Descriptors: *Wetlands, *Flooding, *Vegetation, Water depth, Wildlife habitats, Marsh management, Sweden.

The effect of flooding sites of former, periodically flooded water-meadows in northern Sweden was studied in two areas for two and three years, respectively. The vegetation consisted mainly of Equisetum fluviatile L., Carex rostrata Stokes, Carex aquatilis Wahlenb., Comarum palustre L., and Lysimachia thyrsiflora L. Increase in water depth caused a significant decrease in the species number. Carex rostrata, C. aquatilis and Lysimachia thyrsiflora were almost eliminated (although Carex aquatilis seemed to be somewhat more tolerant to the increased water depth). Equisetum fluviatile was unaffected, except for increase in shoot length, while the effect of flooding on Comarum palustre was intermediate. The practical application of flooding is discussed with regard to habitat management for waterfowl. (Author's abstract)

THE RESPONSE OF INTERSTITIAL AMMONIUM IN EELGRASS (ZOSTERA MARINA L.) BEDS TO ENVIRONMENTAL PERTURBATIONS,
Harbor Branch Foundation, Inc., Fort Pierce, FL.
F. T. Short.
Journal of Experimental Marine Biology and Ecology, Vol. 68, No. 2, p 195-208, April, 1983. 7 Fig, 2 Tab, 26 Ref. OCR-74-13457A02, OCE-77-27050.

Descriptors: *Eelgrass, *Marine sediments, *Ammonium, Seagrasses, Nitrogen uptake, Scour, Substrates, Nutrients.

Natural and human-induced perturbations of eelgrass (Zostera marina L.) beds were used to examine the interaction between the sediment interstitial ammonium pool and nitrogen uptake by the plants. The perturbations included: a natural destruction of an eelgrass bed by ice damage (scouring), followed by recolonization by eelgrass; colonization of introduced foreign substratum by eelgras
removal; and sealing the sediment surface. Ee
colonization of unvegetated areas was acc
nied by a substantial decrease in the inter
ammonium pool over a 4-yr period. The ch
in interstitial ammonium and shoot density d
colonization support an already determined
tionship between shoot density and ammo
pool measurements. In field perturbation e
ments, removing eelgrass leaves and sealin
sediment surface altered the flux of ammo
from the interstitial ammonium pool, and re
in a rapid increase in interstitial ammonium
centrations. Measurements of ammonium acc
lation under the various perturbation cond
and a control permitted calculation of the sed
ammonium flux. These estimates include upta
eelgrass roots, regeneration in the root zone
diffusion from the sediments. Nitrogen limi
was observed in some eelgrass beds. (Moore

FOUND WATER AT 200 GALLONS/YARD.
American City and County, Vol. 98, No. 8, p 58-59, August, 1983. 3 Fig.

Descriptors: *Dredging, *Reservoirs, *Sludge lagoons, Portsmouth, Virginia, Lake Meade, Water storage, Sediments, Dredging.

A 4.0 billion gallon impoundment system serves about 120,000 people in Portsmouth and parts of Suffolk and Chesapeake, Virginia. Daming of the Nansemond River in the later 1950s to form Lake Meade blocked the natural dispersion of sedimentation from the water treatment plant. Sludge began to collect in the Lake, gradually reducing its useful capacity. Several methods for removing the sludge were contemplated. The method chosen called for use of a shallow-draft dredge moved by conventional over-the-road flatbed trailer. Removal rates ranged up to 2,000 GPM and up to 120 cu yd/hr during the dredging operation. The slurry flowed by gravity to the 250,000 gallon holding tank until it could be pumped to the city's sludge treatment lagoon. Dredging operations continued for 10 hours a day, six days a week. In 80 calendar days the work was completed. Over 30,000 cu yd of material had been removed. For every yard of material removed, 200 gallons of water capacity were gained. (Baker-IVI)

3C. Use Of Water Of Impaired Quality

WATER REUSE IN WATER SURPLUS ENVIRONMENT,
Memphis State Univ., TN.
J. W. Smith, and C. Ritter.
Journal of Water Resources Planning and Management, Vol. 109, No. 3, p 223-235, July, 1983. 7 Fig, 8 Tab, 2 Ref.

Descriptors: *Water reuse, *Water substitution, Cost analysis, Computers, Industrial water, Water use, Water allocation.

Water reuse or substitution for high quality water in a water surplus area can be economical and a long-term protection against shortages and land subsidence. Cost optimization using computer assisted analysis of use allocation between users ('sinks') and supply ('sources') demonstrated a viable analysis procedure as well as the potential for water substitution. Secondary water use by industry is more attractive in an urban environment than irrigation or ground water recharge and may best be suited for industrial parks or complexes where a dual system (process and domestic) can be installed. WASTEWATER REUSE AND RECYCLE IN PETROLEUM REFINERIES,
JRB Associates, Inc., Paramus, NJ.
B. S. Langer.
Chemical Engineering Progress, Vol. 79, No. 5, p 67-76, May, 1983. 1 Fig, 9 Tab.

Descriptors: *Water reuse, *Wastewater treatment, Reclaimed water, Petroleum industry, Wastewater renovation, Water use, Water supply development, Industrial wastes, Cooling towers.

Wastewater reuse and recycling techniques were studied at 15 petroleum refineries. Three of the refineries were selected for their exemplary reuse and recycle techniques, and the technologies used were investigated for their applicability at the remaining 12 facilities. Feasible reuse and recycle techniques were identified to reduce wastewater discharge and estimates of the associated costs were considered. Boiler feed waters involve large volumes of water, of which an estimated 37% is lost to the sewer in various forms, such as clean and scour condensate, boiler blowdown, and pretreatment wastes such as filter backwash, clarifier sludge, and softening regenerant. Steam condensate and vent loss elimination are also areas for considerable savings. Condensate recovery is the most economically attractive reduction technique studied. At refineries using cooling towers, the cooling tower blowdown streams amounted to one-third of the total refinery process wastewaters. Some refineries rely on air cooling to supply 20 to 40% of their cooling needs by Btu. Most refineries tend to pay insufficient attention to cooling water systems management. Some modifications which may be commonly applied include recycling cooling water from pumps, compressors and sample boxes that use blowdown; replacing existing oil-leaking pump gland packing with mechanical seals to permit collection and recycle of blowdown to cooling tower; reducing use of pump gland cooling water where pressure overused or eliminate service completely; and upgrade maintenance of existing systems to reduce leakage and sump overflow. Of the 12 refineries studied, potential areas for additional reuse of treated effluent were found at eight, for which possible flow reduction alternatives were identified. An average of 45% of the total process generated wastewaters could be reused for various purposes after end-of-pipe treatment at ten of the twelve refineries. (Baker-IVI)

WATER CONSERVATION AND REUSE AT COAL-FIRED POWER PLANTS,
Burns and McDonnell, Kansas City, MO.
F. L. Shorney.
Journal of Water Resources Planning and Management, Vol. 109, No. 4, p 345-359, October, 1983. 2 Fig, 8 Tab, 2 Ref.

Descriptors: *Water conservation, *Water reuse, Power plants, Cooling water, Wastewater renovation, Wastewater treatment, Water requirements, Water treatment, Wastewater disposal.

Water conservation and reuse concepts which have been used at several major power plants (200 MW or larger) in the southwest, southeast, west, and mid-west United States are described. These plants typically employ wet-type cooling towers and most use wet-type, closed-loop sulfur dioxide

absorbers. All plants have limited discharge or zero liquid discharge site requirements. Basic concepts include the on-site storage of raw water and wastewater for operating flexibility, the treatment of raw water to optimize water use, water conservation in mechanical systems to minimize blowdown or waste streams, direct wastewater reuse and indirect reuse with wastewater treatment to reduce raw water requirements and site discharges, and water management to control the overall plant water balance. EFFECTS OF PESTICIDES ON PURE AND MIXED SPECIES CULTURES OF SALT MARSH POOL ALGAE,
Northeastern Univ., Boston, MA. Dept. of Biology.
M. Maly, and E. Ruber.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 1, p 464-472, April, 1983. 6 Tab, 9 Ref. RR07143.

*Algal growth, *Pesticides, Carbaryl, Salt marshes, Tidal marshes, Marshes, Diatoms, Chlorophyta, Dinoflagellates, Water pollution effects.

The general sensitivity of three diatom species, Nitzchia closterium, Amphora coffeaformis v. borealis, and Amphiprora sp.; green alga, Chlorococcum sp.; and a dinoflagellate, Gonyzulax sp., to five pesticides (temephos, propoxur, chlorpyrifos, malathion, and carbaryl) was investigated. Carbaryl was the most generally toxic of the five insecticides tested, and was used for further studies. Amphiprora was the most broadly sensitive alga followed by Chlorococcum. Gonyaulax, resistant to a concentration of 10 ppm, was the least affected of the species. Amphiprora had lowered growth with concentrations of 10, 21 and 1 ppm, but the effect on growth lasted only 4 hr with 2 and 1 ppm. Amphora was slightly more sensitive than the other species with growth depressed by 10, 2, and 1 ppm and this effect persisted through the entire 96 hr test period. Growth of Chlorococcum was depressed for 96 hr at 10, 2, and 1 ppm of carbaryl. In comparing results from single to multispecies cultures experiments, it becomes apparent that one cannot predict the effect of carbaryl on components of multispecies cultures solely from its effects in single-species cultures. All four species are inhibited by carbaryl at 2 ppm in single-species culture but in multispecies cultures only two are inhibited. Also, the rank order of species sensitivity differs between the two experimental designs. Amphiprora is more sensitive in the multispecies communities and Chlorococcum in single species cultures. Similarly, results after 2 and 4 day tests are not necessarily good indicators of longer term outcomes. (Baker-IVI)

RESERVOIR OPERATION BY LINEAR AND DYNAMIC PROGRAMMING,
California Univ., Davis.
M. A. Marino, and B. Mohammadi.
Journal of Water Resources Planning and Management, Vol. 109, No. 4, p 303-319, October, 1983. 6 Fig, 4 Tab, 14 Ref. CAD-LAW-4116-H.

Descriptors: *Reservoir operation, *Computers, Water demand, Flow, Forecasting, Computer models, Mathematical models.

The operation of reservoirs often requires frequent updating of the results of the operation model. This is mainly because of errors involved in forecasting the natural inflows to the reservoirs or demands for water and energy or both. Current models used for operation usually require the use of large computers because of their core-storage and computation-time requirements. Frequent use of such models for the purpose of updating will often result in high computation cost and usually involves long turnaround times. An efficient algorithm is presented for the monthly operation of a system of two parallel multipurpose reservoirs that is solved with a minicomputer. The operation model is applied to Shasta and Folsom reservoirs of the California Central Valley Project. The formulation of the mathematical model itself allows for optimization of both municipal and industrial water and energy. While the addition of other objectives will increase the size of the dynamic programming, and will require more core storage, the addition of more reservoirs will not affect the dynamic programming but causes the linear programming size to increase linearly. TUNISIA'S BOURGUIBA DAM AIDS REGIONAL DEVELOPMENT.
International Water Power and Dam Construction, Vol. 35, No. 8, p 30-32, August, 1983. 3 Fig.

Descriptors: *Water resources development, *Dam construction, Tunisia, Bourguiba Dam, Environmental effects, Sidi Saad project, Saddle dam, Irrigation, Spillways.

The Bourguiba Dam in Tunisia was built at Sidi Saad on the Zeroud wadi to control the flash floods that have threatened the regions's central plain and the city of Kairouan. The water in the reservoir will recharge water tables and irrigate 4000 ha of land. The Zeroud wadi drains a basin of 8572 sq km that encompasses the southeastern slopes of the Dorsale range and the eastern tip of the Atlas range. The Merguellil wade drains a basin of 1140 sq km and flows directly to Kairouan across the central plain. The Sidi Saad project began in 1976. In 1980 Tunisia began a reforestation scheme which will continue for 15 years. The central element of the Sidi Saad project is a main dam, 70 m high and 560 m long, with its crest at elevation 302.5, built at the narrowest part of the Zeroud gorge 2 km upstream from the point where the wadi enters the plain. It is an earthfill dam with an impervious clay core, and with its upstream and downstream coffer dams, called for 4,438,000 cu m of fill material. The shells are made up mainly of silts and clays and the transition and filter zones of granular materials. A 100 m band of clay marl on the left bank extends into the river bed and reappears on the right bank, so the core material was placed downstream of it, and a grout curtain, reaching as deep as 100 m in places was injected into the foundation to make sure that the marl would remain impervious and that no water could seep under the dam. A saddle dam, 48 m high and 520 m long with its crest at elevation 302.5 closes the gorge on the right bank. An open concrete spillway with a capacity of 6900 cu m/sec is built in an 80 m deep cut through the right bank mountain between the two dams. The two dams create a reservoir with a capacity of 1,994,000 cu m. A desilting system, integrated with the temporary diversion tunnel, is working well and efficiently on the density current principle. (Baker-IVI)

WHY NOT CHARGE FOR STORM DRAINAGE,
P. Gallagher, and D. Laredo.
American City and County, Vol. 98, No. 5, p 45-46, May, 1983.

Descriptors: *Runoff, *Storm runoff, *Drainage, Storm drains, Storm wastewater, Land development.

Stormwater runoff is often increased due to residential and industrial land development. Local governments often try to deal with these problems through traditional methods of stormwater drainage facilities using ad valorem property tax funds. Tight municipal budgets are causing some communities to consider financing stormwater drainage systems through user charges and developer contributions. This necessitates viewing the stormwater drainage as a utility. Users of a drainage system are the properties adding stormwater runoff, while the beneficiaries are the properties protected from flooding. Users of storm drainage systems have a legal duty, although not as clearly recognized as the duty to p wastewater treatment. The duty of land dev and property owners generally is to protect stream properties from higher than natural rates. A fiscally independent drainage utility ates both capital and operating funds from other than property taxes. A comprehensive by-basin drainage plan should be prepared to near-term and long-term drainage system im ments. The master drainage plan should enco not only the drainage basins within the loca ernment's jurisdiction, but also basins or p of basins that are outside the jurisdiction but drainage requirements within it. One prima vantage of utility-type financing, as oppo traditional methods of financing, is the crea a new revenue stream. Another advantage equity of recovering the costs of the service those who use it. (Baker-IVI)

the environmental impacts of logging and are caused by changes in the hydrologic of slopes after disturbances. This study ducted to evaluate changes in inflow, stor- age, and outflow for 3-year periods before and after clearcut logging and wildfire on two steep, granitic microwatersheds in Idaho. Clearcutting alone and clearcutting plus wildfire increased annual peak snow water equivalent and snowmelt rates an average of 41% and 30%, respectively. The greater volume and rate of snowmelt caused respective increases in the peak piezometric rise and in total piezometric storage, amounting to 47% and 27%. Accordingly, the total volume of subsurface flow intercepted by the roadcut was increased 96% and was accompanied by 27% greater peak flow rates. None of the above responses were detectable on an adjacent watershed that was burned by wildfire alone. Evapotranspiration was reduced on both watersheds after clearcutting or wildfire, as indicated by increases in the unsaturated soil water content at the end of the growing season amounting to 44 and 72% respectively. Accelerated mass erosion on clearcut slopes, and accelerated surface and mass erosion on roads and in channels below roads, can result from such changes. (Author's abstract)

4D. Watershed Protection

SOIL EROSION: ECONOMIC AND TECHNOLOGICAL INTERFACES,

Department of Agriculture, Washington, DC.
G. S. Bridge.
Agricultural Engineering, Vol. 64, No. 8, p 13-16, August, 1983. 1 Fig, 2 Tab.

Descriptors: *Soil erosion, *Water conservation, *Regulations, Federal jurisdiction, Policy making, State jurisdiction.

Agriculture is the nation's biggest water user, accounting for about 50% of total freshwater withdrawals and over 80% of total consumption. While most of the country has enough surface water to meet demands most years, the High Plains area experiences the most extensive chronic water shortages. This is significant as considerable amounts of groundwater are being withdrawn for irrigation and other uses. In the High Plains, the increased cost of pumping water from greater depths is forcing many farmers to stop irrigating. Water pollution affects, to some degree, 95% of all US drainage basins. Non-point source pollution from agricultural lands is a major contributor to this problem. The USDA has developed a set of policies, priorities and initiatives to guide federal assistance activities for the next several years. Local and state governments will be encouraged to become full partners in developing and implementing conservation programs. (Baker-IVI)

5. WATER QUALITY MANAGEMENT AND PROTECTION

5A. Identification Of Pollutants

AN IMPROVEMENT FOR THE CONCENTRATION OF MICROPOLLUTANTS IN THE MARINE ENVIRONMENT BY USING A BACTERIA STRAIN WITH A MEMBRANE FILTER SYSTEM,

System Science Consultants, Inc., Tokyo (Japan).
I. Allahpichay, M. Mishima, and T. Yoshida.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 3, p 253-260, March 1983. 5 Fig, 3 Tab, 13 Ref.

Descriptors: *Pollutant identification, Bacteria, Membrane filters, Filters, Marine environment, Biological magnification, DDT, Polychlorinated biphenyls.

Attempts were made to concentrate PCBs and DDT residues by a strain of bacteria and then to filter out the bacteria on a millipore filter using the model apparatus designed for this study. A Pseudomonas sp. was chosen as it represents one of the most dominant forms in the aquatic system. The selected strain demonstrated a bioconcentration ability in the range of 40-50% for PCBs and p,p-DDT in 3 hr exposures and attaining 80% for 12 hour exposures. The PCBs and DDT residues were not fully solubilized in the filtered seawater in spite of overnight stirring. The biofilter showed better recoveries than a membrane filter. There is a potential for PCBs and DDT residues in traces to be pre-concentrated using membrane filter and bacteria. Persistent pollutants adsorbed on to suspended particulates could be identified and quantified. Water samples assayed by this method showed traces of PCBs and p,p-DDE at concentrations sufficiently low that they were sensitive to the analytical method but could not be quantified, especially the PCBs. In trials of Tokyo Bay coastal waters, the p,-p-DDE adsorbed by the membrane filter-suspended particulates and the biofilter could be detected. This method could be used for evaluating the quality of water where PCBs and DDT residues could be present in concentrations below those toxic to aquatic life. (Baker-IVI)

DETECTION LIMITS OF A BIOLOGICAL MONITORING SYSTEM FOR CHEMICAL WATER POLLUTION BASED ON MUSSEL ACTIVITY,

Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
W. Slooff, D. de Zwart, and J. M. Marquenie.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 1, p 400-405, April, 1983. 3 Tab, 15 Ref.

Descriptors: *Pollutant identification, *Monitoring, *Mussels, Mollusks, Organic compounds, Copper, Sulfates, Cadmium, Phenols, Cyanide, Industrial wastes.

An automatic early warning system for chemical water pollution is presented based on the valve response of the fresh water mussel, Dreissena polymorpha. To detect the behavior of mussels in terms of shell valve movements an electronic device was used. In this device one valve is fixed whereas the other valve transfers its action to a coil moving in an oscillating electromagnetic field generated by a fixed coil. The current in the receiving coil is subsequently converted to a voltage proportional to the valve displacement. The following chemicals resulted in a valve closure response: copper (sulfate), trichloroethylene, gamma-hexachlorocyclohexane, pentachlorophenol, hexachlorobutadiene, chloroform, ephnol, xylene, and cadmium (chloride). Although the biomonitor is probably somewhat less sensitive to toxicants than the system based on fish respiration, the mussel system is less susceptible to noise problems that may result in false alarms at an unacceptable rate. Changes in temperature and photoperiod do not interfere with the behavior of mussels. The mussel monitor is easier to handle as the replacement of the organisms takes less time, no individual control recordings are needed and feeding does not interrupt the measurements. Used in natural waters the mussels are self-maintaining. Hence, the mussel system is more feasible for wide-spread industrial applications that the fish respiration as it is more reliable and can be installed and operated at about 20% lower costs. USE OF FLUORESCENCE SPECTROSCOPY FOR MONITORING PETROLEUM HYDROCARBON CONTAMINATION IN ESTUARINE AND OCEAN WATERS,

Adelaide Univ. (Australia). Dept. of Physical and Inorganic Chemistry.
W. A. Maher.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 1, p 413-419, April, 1983. 2 Fig, 2 Tab, 9 Ref.

Descriptors: *Monitoring, *Industrial wastes, *Fluorescence, Oil industry, Hydrocarbons, Organic compounds, Estuarine environment, Pollutant identification, Naphthalene.

Aromatic hydrocarbons were extracted from water samples after adjustment of pH to 4.0-5.0. The aromatic hydrocarbon content of the extracts was estimated by fluorescence emission spectroscopy. Solutions were excited at 300 nm, the emission scanned from 310-500 nm and the fluorescence emission intensity of the main peaks measured and reported as equivalents of m-terphenyl and chrysene. One liter samples of seawater were spiked with 1 microgram of either Tapis Bulai crude, Barrow Island crude or lubricating oil and analyzed by extraction and spectrofluorimetry. Recoveries of all oils were greater than 95%. Water samples were also collected from locations near potential sources of petroleum hydrocarbon inputs. The fluorescence emission intensity of extracts of 330 nm and 380 nm varied depending on the source of petroleum hydrocarbons. Measurement at 330 nm gave a better indication of petroleum discharges near the boat marine and sewerage inlet. Measurement at 330 nm and 380 was more suitable for monitoring potential inputs from oil refineries and storm water drains. The study showed that if fluorescence spectroscopy is to be used to monitor petroleum contamination of estuarine and sea waters, the fluorescence emission of extracts should be measured at least at two wavelengths to allow the detection of fuel oil, lubricating oil and crude oil inputs. Thus the measurement of the fluorescence emission of water extracts provides a rapid means of monitoring petroleum hydrocarbon contamination. (Baker-IVI)

X-RAY MICROANALYSIS OF PLANKTIC DIATOMS IN IN SITU STUDIES OF METAL POLLUTION,
Uppsala Univ. (Sweden). Inst. of Ecological Botany.
G. Lindahl, K. Wallstrom, G. M. Roomans, and M. Pedersen.
Botanica Marina, Vol. 26, No. 8, p 367-373, August, 1983. 5 Fig, 3 Tab, 13 Ref.

Descriptors: *Metals, *Diatoms, *X-ray spectroscopy, Microscopic anaylsis, Plankton, Heavy metals, Water pollution effects, Seasonal variation, Sweden.

X-ray microanalysis was applied to in situ studies of metal accumulation in plankton organisms, especially diatoms, in Skellefte Bay, a heavily polluted coastal area in northern Sweden. The metal load of the area is in the approximate order Fe>As>Mn>Zn>Cu>Pb>Cd. The metal accumulation in the plankton organisms was not proportional to the relative metal content in the water. Fe and Cu, which were most frequently accumulated, were found in connection to the silica frustules of the diatoms, probably as a result of ion exchange between the metals and the algae. Seasonal differences in the frequency of metal accumulation are most probably an effect of changes in the environmental conditions mainly due to variations in fresh water influence. Some unusual contaminants were found (such as Zr) which would probably have been missed by more conventional methods of analysis. The large variations within a single sample make the analysis of many cells necessary before representative values for the overall composition of the sample are obtained. Macroscopic comparisons between plankton samples are probably still best carried out by more conventional methods of analysis. X-ray microanalysis is, however, clearly a valuable tool in the interpretation of such comparisons. (Moore-IVI)

QUALITY CONTROL IN WATER ANALYSES,
Weston (Roy F.), Inc., West Chester, PA
C. J. Kirchmer
Environmental Science and Technology, Vol. 17, No. 4, p 174-186, April, 1983. 5 Fig, 1 Tab, 16 Ref.

Descriptors: *Water analysis, *Standards, Quality control, Testing procedures, Laboratories.

Although quality control has become an accepted and even required practice in water analysis labs, the definitions and principles underlying the practice of quality control still need to be critically evaluated. A distinction must be made between the errors of the analytical method and the errors of results. Great emphasis must be placed on specifying methods accurately and completely. There are six possible sources of bias or systematic error in water analyses: unrepresentative sampling, instability of samples between sampling and analysis, interference effects, biased calibration, a biased blank correction, and the inability to determine all forms of the determinand. A survey of standard methods and government approved methods of water analysis in the US indicates that the possibility of biased calibration curves or biased calibration factors resulting from the use of different analytical procedures for standards and samples is not widely recognized. Accurate analyses depend primarily on the implementation of a well conceived within the laboratory quality control program involving two stages: preliminary error estimation and routine quality control from the use of appropriate control charts. Between lab tests should involve two stages also: comparison of standard solutions used by each lab with a standard distributed by coordinating lab and the collaborative analysis of samples distributed to all labs by a coordinating lab. (Baker-IVI)

APPLICATION OF CONTINUOUS-FLOW ULTRAFILTRATION AND COMPETING LIGAND/DIFFERENTIAL SPECTROPHOTOMETRY FOR MEASUREMENT OF HEAVY METALS COMPLEXATION BY DISSOLVED ORGANIC MATTER,
Illinois State Water Survey Div., Champaign.
J. R. Tuschall, Jr., and P. L. Brezonik.
Analytica Chimica Acta, Vol. 149, p 47-58, May, 1983. 3 Fig, 2 Tab, 29 Ref. PFR-78-19199, EPA-R-806286020.

Descriptors: *Organic matter, *Heavy metals, *Metal complexes, Ultrafiltration, Spectrophotometry, Polyaspartic acid, Swamps, Copper, Metal binding.

Continuous ultrafiltration and competing ligand/differential spectrophotometric methods were developed to quantify metal complexation by naturally occurring aquatic organic matter. Results for copper(II) ion complexation by organic matter in two swamp waters and by a model compound (polyaspartic acid) were compared to values obtained by the established ion-selective electrode method. Copper(II) solution was added, and the parameters used to quantify complexation were the metal-binding capacity of the organic matter and conditional stability constant (beta') of the metal-organic complexes. Copper complexed strongly with the organic material at pH 6.25; beta' values ranged from 10(5.3) to 10(8.5). Values obtained with the three procedures compared well. (Author's abstract)

ZONE TRAPPING IN FLOW INJECTI ANALYSIS; SPECTROPHOTOMETRIC TERMINATION OF LOW LEVELS OF AMM NIUM ION IN NATURAL WATERS,
Centro de Energia Nuclear na Agricultura, Pir caba (Brazil)
F. J. Krug, B. F. Reis, M. F. Gine, E. A. G. Zagatto, and J. R. Ferreira.
Analytica Chimica Acta, Vol. 151, p 39-48, 198 Fig, 1 Tab, 17 Ref.

Descriptors: *Ammonium, *Flow injection ana sis, *Spectrophotometry, Water analysis, Z trapping, Metals, Interference.

In flow injection analysis, selected portion o processed sample zone can be removed and, aft predetermined period of time reintroduced into same carrier stream. This zone-trapped technic easily applied, is suitable for methods based relatively slow chemical reactions in which se tivity or sampling rate is critical. It has so advantages over the stopped-flow and intermitte flow approached. The technique was studied fo model system without chemical reaction, and v then applied in a sensitive spectrophotomet method for the determination of ammonium ion natural waters, based on a modified Berthelot re tion. In zone trapping, the main portion of reacting sample zone is retained in a 38 C wa bath so that about 80% complete reaction achieved without limiting the sampling rate. T proposed method is suitable for 90-100 me urements per hour with a relative standard de ation of 0.5% for a typical sample (0.15 mg ammonium). Beer's law is followed up to 1 mg and the detection limit is 5 micro g/l. Interferenc of metals are overcome with EDTA. The resu for waters agree well with those obtained by standard manual procedure. (Author's abstract)

DETERMINATION OF PHOSPHORUS IN NATURAL WATERS BY LONG-CAPILLARY-CELL ABSORPTION SPECTROMETRY,
Tokyo Univ. (Japan). Dept. of Chemistry.
W. Lei, K. Fujiwara, and K. Fuwa.
Analytical Chemistry, Vol. 55, No. 6, p 951-955, May, 1983. 4 Fig, 6 Tab, 13 Ref.

Descriptors: *Colorimetry, *Phosphorus, Water analysis, Sea water, Natural waters, Lake Katsumigaura, Japan.

Use of a long capillary cell (LCC) effectively enhances the detection power of ordinary colorimetry. The minimum necessary volume of sample is about 1-3 mL. By application of this method to molybdenum-blue colorimetry, 5 pg/mL of phosphorus is detectable. Phosphorus concentrations less than 1 ng/mL in seawater and lake water are successfully determined by using LCC. LCC produced good coincidence with values obtained for ordinary colorimetry in studies on phosphorus concentrations in Lake Kasumigaura (Japan). The advantages of LCC are low cost of construction, simple manipulation, and high stability of obtained signal. Although the use of the present system is limited to the visible region due to poor internal reflection of LCC at shorter wavelengths, the method is extensively applicable in colorimetry. (Moore-IVI)

DETERMINATION OF TRIALKYLLEAD COMPOUNDS IN WATER BY EXTRACTION AND GRAPHITE FURNACE ATOMIC ABSORPTION SPECTROMETRY,
Antwerp Univ., Wilrijk (Belgium). Dept. of Chemistry.
W. R. A. De Jonghe, W. E. Van Mol, and F. C. Adams.
Analytical Chemistry, Vol. 55, No. 7, p 1050-1054, June, 1983. 5 Fig, 6 Tab, 34 Ref.

Descriptors: *Trialkyllead compounds, *Atomic absorption spectrometry, Lead compounds, Water pollution, Light, Extraction.

A simple extraction procedure is described for the sensitive determination of traces of trialkyllead compounds in water. After enrichment of the sample by a fast vacuum distillation technique and saturation of the residual volume with sodium chloride, the analytes are extracted in chloroform. By incorporation of specific purification steps, interference from other forms of organic and inorganic lead is completely eliminated. The final chloroform extract is treated with a sulfuric acid solution in order to transfer the trialkyllead compounds present back into an aqueous solution. The analysis is completed by graphite furnace atomic absorption spectrometry. Under normal laboratory conditions, a detection limit of 0.02 micro g can be achieved with 1-L samples. The method was developed to investigate the occurrence of trialkyllead compounds in environmental water samples. Experiments with spiked lake water have established that there is a considerable loss of initially added triethyllead chloride upon exposure to sunlight, while trimethyllead remains fairly stable. (Author's abstract)

DETERMINATION OF ARSENIC AND PHOSPHORUS COMPOUNDS IN GROUNDWATER WITH REDUCED MOLYBDENUM BLUE,
Wisconsin Univ.-Madison. Water Chemistry Lab.
R. E. Stauffer.
Analytical Chemistry, Vol. 55, No. 8, p 1205-1210, July, 1983. 2 Fig, 4 Tab, 30 Ref. R805281010.

Descriptors: *Arsenic, *Phosphorus, *Colorimetry, Molybdenum blue, Groundwater, Water analysis, Arsenic compounds, Phosphorus compounds, Silica, Interference, Fluoride.

Chemical studies were made to optimize reduced molybdenum blue for arsenic and phosphorus determinations in chemically diverse groundwaters. Phosphate strongly catalyzes the development of the arsenic(V) molybdate complex; Increasing H(+) or H(+):Mo retards complexation, but the effect is greater for the potentially interfering silicomolybdate complex. The oxidation of As(III) to As(V) by iodate partially inhibits the subsequent color development of silica. Iodide has no effect. Fluoride ion partially suppresses silica color development, probably because of competetive Si-F complexing at low pH. The molybdate responses of As(V), P, and SiO2 mixtures are not color additive. Optimum reaction conditions are H(+) = 0.30 N; H(+):Mo = 88 for arsenic and phosphorus determinations in the presence of silica. Silica is an important analytical interference for the lower H(+) and H(+):Mo conditions recommended by several popular procedures. (Author's abstract)

CATION-EXCHANGE CONCENTRATION OF BASIC ORGANIC COMPOUNDS FROM AQUEOUS SOLUTION,
Ames Lab., IA.
J. R. Kaczvinsky, Jr., K. Saltoh, and J. S. Fritz.
Analytical Chemistry, Vol. 55, No. 8, p 1210-1215, July, 1983. 2 Fig, 3 Tab, 33 Ref. CHE-7906108.

Descriptors: *Cation-exchange resin, *Organic compounds, Water analysis, Wastewater analysis, Gas chromatography.

A macroreticular poly(styrene-divinylbenzene) cation-exchange resin is prepared. An aqueous sample is passed through a column of this resin in the H(+) form and organic bases are taken up as cations. Washings with methanol and ethyl ether remove sorbed neutral and acidic compounds. Ammonia gas is introduced into the column prior to elution of the basic organics with either methanol or ethyl ether containing ammonia. The eluate is concentrated by evaporation, and the concentrated sample is analyzed by gas chromatography. Over 50 organic bases are recovered from water at the 1 ppm and 50 ppb levels. Recoveries of over 85% are achieved for most of the compounds studied with at least one of the eluents. The resin procedure shows improved recoveries and reproducibility over a simple ether extraction procedure. Real samples of river water, shale process water, and supernatant from an agricultural chemical disposal pit are analyzed for basic organic material by using the resin procedure. (Author's abstract)

PRECONCENTRATION OF TRACE ELEMENTS IN NATURAL WATER WITH CELLULOSE PIPERAZINEDITHIOCARBOXYLATE AND DETERMINATION BY NEUTRON ACTIVATION ANALYSIS,
Public Health Research Inst. of Kobe City (Japan).
S. Imai, M. Murol, and A. Hamaguchi.
Analytical Chemistry, Vol. 55, No. 8, p 1215-1219, July, 1983. 4 Tab, 4 Ref.

Descriptors: *Trace elements, *Neutron activation analysis, *Water analysis, Natural waters, Preconcentration.

To prepare cellulose piperazinedithiocarboxylate (PID), tosylcellulose was reacted with piperazine to give the aminocellulose which was then reacted with carbon disulfide. The preconcentration of the trace elements was accomplished by the PID column operations. Ten liters of river water or spring water sample was passed through the column at a given pH. The packings were taken out of the column, dried at 110 degrees C, and then burned to ashes in a low-temperature plasma asher. The ashes were encapsulated in polyethylene 'rabbits' of the pneumatic tube system and subjected to neutron irradiation in a reactor. Gamma-ray spectrometry was then performed on the irradiated sample and the concentration of 18 elements in natural water samples was determined. This method may be applied to atomic absorbtion spectrophotometry and emission spectrophotometry since PID can be readily decomposed by low-temperature plasma ashing. This method may be recommended as a simple and rapid simultaneous determination method for trace elements in natural water samples. (Moore-IVI)

Analytical Chemistry, Vol. 55, No. 9, p 1471-1479, August, 1983. 5 Fig, 7 Tab, 16 Ref.

Descriptors: *Gas chromatography, *Mass spectrometry, *Organic compounds, Water analysis.

Two general methods for the identification and measurement of organic compounds in water are compared. One method employs packed column chromatography and the other fused silica capillary column chromatography. The two gas chromatography/mass spectrometry (GC/MS) methods use different pH conditions for the liquid-liquid extractions with methylene chloride. Single laboratory total method accuracy and precision data are presented for over 80 analytes in water at the low parts per billion level. With the packed column method, 54% of the analytes have a mean recovery of 70% or more. With the capillary column method, 74% of the analytes have a mean recovery of 70% or greater. Both methods give mean relative standard deviations for concentration measurements of about 20%. (Author's abstract)

DETERMINATION OF HALOGENATED ORGANIC COMPOUNDS IN WATER BY GAS CHROMATOGRAPHY/ATMOSPHERIC PRESSURE HELIUM MICROWAVE-INDUCED PLASMA EMISSION SPECTROMETRY WITH A HEATED DISCHARGE TUBE FOR PYROLYSIS,
Tokyo Univ. (Japan). Dept. of Chemistry.
K. Chiba, and H. Haraguchi.
Analytical Chemistry, Vol. 55, No. 9, p 1504-1508, August, 1983. 5 Fig, 5 Tab, 16 Ref.

Descriptors: *Halogenated hydrocarbons, *Water analysis, *Gas chromatography, Plasma emission spectroscopy, Trihalomethanes, Seawater, Monochlorobenzene, Drinking water, Water pollution.

Gas chromatography/atmospheric pressure helium microwave-induced plasma emission spectrometry has been applied to the determination of halogenated, organic compounds in tap, pond, and river waters and seawater, as well as deionized and distilled waters. A quartz plasma discharge tube of 200 mm length was heated to 900 C for pyrolysis, since a 100 mm long conventional discharge tube without heating showed nonuniform relative responses due to incomplete decomposition of some compounds when it was used to transfer the column effluent to the microwave-induced helium plasma (MIP). Halogenated organic compounds in aqueous samples were collected on an Tenax GC column by a gas purge-and-trap method. Trihalomethane compounds including monochlorobenzene were found at the microgram per liter levels in tap and river waters, while their levels were much lower in pond water and seawater. Deionized and distilled waters also contained halogenated compounds at approximately the same levels as tap water. These results indicate that deionization and distillation processes do not exclude organohalide compounds in tap water. There was no evidence for organoiodine compounds in water (Moore-IVI)

SCALE MORPHOLOGIC RESPONSE TO AROMATIC HYDROCARBONS,
Grambling State Univ., LA. Dept. of Biology
V. Henderson.
Bulletin of Environmental Contamination and Toxicology, Vol. 31, No. 3, p 315-321, September, 1983. 4 Fig, 1 Tab, 11 Ref.

Descriptors: *Fish, *Toxicity, *Hydrocarbons, Fish scales, Fuel, Water pollution effects, Melanophores.

A simple and inexpensive procedure was developed to assess the toxic effects of aromatic hydrocarbons utilizing scales, without sacrificing the fish. Mosquito fish (Gambusia affinis) were exposed to 3.45 mg/l hydrocarbons from the water-soluble fraction of shale-derived JP-4 fuel for 48 hr. Scales from the exposed and unexposed fish were examined by light microscopy and scanning electron microscopy (SEM). The changes observed with the electron microscope manifested themselves in an arborization and an increase in total number of melanophores leading to preponderance of stellate-reticulate melanophores. An increase in pigment was a function of the type and number of melanophores present. Surface cell morphology with SEM provides another parameter for assessing damage to cells. This method can drastically reduce the evaluation time required to assess pollutants. (Moore-IVI)

Descriptors: *Hydrocarbons, *Water analysis, *Sediment analysis, *Extraction, Gas chromatography, Solvents, Sodium chloride, Methanol.

An inert gas stripping method for the extraction of trace amounts of hydrocarbons from water for gas chromatography is improved by the addition of sodium chloride and methanol. The method can also be applied to contaminated sediments analysis. The method was applied to a mixture of 10 hydrocarbons at 20 C with an output of gas of 120 ml/min under the following conditions; (A) without additive, 60 min analysis time; (B) with 10 g/l NaCl, 30 min; with 2 ml/l methanol, 30 min. The analysis time was cut in half with the additives, and the quantities of extracted hydrocarbons are equal or greater than those extracted in condition A. (Moore-IVI)

REDUCTIVE DEHALOGENATIONS OF LOBENZOATES BY ANAEROBIC LAKE MENT MICROORGANISMS,
Michigan State Univ., East Lansing. Dept. of and Soil Sciences.
A. Horowitz, J. M. Suflita, and J. M. Tiedje.
Applied and Environmental Microbiology, 45, No. 5, p 1459-1465, May, 1983. 6 Fig, 1 Ta Ref.

Descriptors: *Microorganisms, *Dehalogen *Halobenzoates, Lake sediments, Halogens, mation, Metabolism, Methane, Chlorobenz Bromobenzoates, Idobenzoates, Anaerobic tions.

Methane-producing freshwater lake sediment found to dehalogenate chloro-, bromo-, and benzoates by a reductive reaction in which halogen was replaced by a hydrogen atom. identity of the dehalogenated products was firmed by mass spectrometry, nuclear mag resonance, or cochromatography. Removal o halogens to produce benzoate was nece before mineralization to CH4 + CO2 could o The dehalogenation occurred after a lag p which lasted from 1 week to more than 6 mo depending on the chemical. Dehalogenation not observed in the absence of CH4 produc and it was inhibited by the addition of 20% Once sediment was acclimated to haloben dehalogenation, new additions of the haloben were degraded without lag. Acclimation wa served regardless of whether the parent subst were eventually mineralized to CH4 + CO2. ment acclimated to bromo- and chloroben degradation generally metabolized bromo- chlorobenzoates, but sediment acclimated to benzoate degradation only metabolized iodo zoate. Prior acclimation of sediment to ben decomposition did not alter the pattern of de genation, and sediment acclimated to dehalog tion was not concurrently acclimated to ben degradation. The presence of this apparent s ficity, the lag period, and subsequent acclima together with our findings of the absence of d logenation in sterile sediments and by sedim previously incubated at greater than or equal degrees C, suggests that this reaction was bio cally catalyzed. Apparently, a pathway for reductive dehalogenation of aryl halides is pr in anaerobic microorganisms of this methanog sediment. (Author's abstract)

APPLICATION OF HIGH-SPEED LIQUID CHROMATOGRAPHY USING SOLVENT EXTRACTION OF THE MOLYBDOHETEROPOLY YELLOW TO THE DETERMINATION OF MICROAMOUNTS OF PHOSPHORUS IN WASTE WATERS,
Hamamatsu Univ. (Japan). School of Medicine.
N. Sakurai, K. Kadohata, and N. Ichinose.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 314, No. 1, p 634-637, April, 1983. 4 Fig, 5 Tab, 5 Ref.

Descriptors: *High-speed liquid chromatography, *Phosphorus, *Wastewater analysis, Interference, Silicon compounds, Molybdoheteropoly yellow, Solvent extraction.

In the determination of phosphorus in wastewaters, the usual method is the spectrophotometry of molybdoheteropoly blue, but this is complicated because the color of silico molybdoheteropoly blue, developed simultaneously, can interfere with the determination. A method for determining microamounts of phosphorus in wastewater by HPLC is based on the solvent extraction of molybdoheteropoly yellow with methyl propionate. The corresponding silicon compound is not extracted into this solvent. Thus, the interference by silicon is excluded. Microamounts of phosphorus can be determined not only in waste water but also in river water rapidly and exactly. The limit of detection is 0.5 ppm, and the coefficient of variation is 4.7%. (Moore-IVI)

Descriptors: *Nonionic surfactants, *Spectrophotometry, Solvent extraction, Sodium picrate, Surfactants, Water analysis, Interference.

The determination of traces of polyoxyethylene non-ionic surfactants (APE) in water is based on the formation of a complex between APE and sodium picrate. The complex is extracted into 1,2-dichloroethane and the absorbance of the solvent phase is measured at 378 nm. Quarternary ammonium surfactants and iron(III) caused positive errors, but the interference due to iron(III) was effectively masked with CyDTA. Humic acids, anionic surfactants, common cations and anions did not interfere. For general type APE (n = 8 - 13) the apparent molar absorptivities of the picrate complexes were 5 - 7 times larger than those of cobalt thiocyanate complexes. Various polyethoxylated compounds in the range of n from 9 to 85 in the same quantity were almost the same in absorbance; recoveries of APE were about 93 - 107%. Therefore this method is quite usable. As little as 0.04 ppm can be determined. In a river water sample 0.04-0.05 ppm and in another case 0.34 ppm of APE were found. (Author's abstract)

A NEW CALIBRATION METHOD FOR THE NITRATE TRACE DETERMINATION IN WATER SAMPLES (EIN NEUES EICHVERFAHREN ZUR NITRAT-SPURENBESTIMMUNG IN WASSERPROBEN),
Regensburg Univ. (Germany, F.R.). Inst. fuer Anorganische Chemie.
K. G. Heumann, and M. Unger.
Fresenius Zeitschrift fur Analytische Chemie, Vol. 315, No. 5, p 454-458, July, 1983. 2 Fig, 4 Tab, 20 Ref.

Descriptors: *Nitrates, *Mass spectrometry, Isotope dilution analysis, Water analysis, Ionization, Drinking water.

The development of a new method for the mass spectrometric isotope dilution analysis of nitrate traces is described. The formation of negative NO2(-) thermal ions at a hot metal surface is used for the mass spectrometric detection. The optimum conditions for the ionization process depending on the filament material, the filament temperature and the sample compound are discussed. Enriched N15 labeled NO3(-) is used as a spike solution. By this method the nitrate traces could be analyzed down to the ng/g-level. In the concentration range 10-30 micro g/g which is especially important for drinking water, the relative external standard deviation of the analyses is 0.1%. As the described isotope dilution technique is a definitive method without any external standardization it is especially suitable as a calibration method. (Author's abstract)

Descriptors: *Groundwater contamination, *Fate of pollutants, Methanogenesis, Phenols, Methane, Coal tar, Industrial wastes.

Groundwater in St. Louis Park, Minnesota has been contaminated by the operation of a coal tar distillation and wood treatment facility. Water samples were collected at three wells from the near-surface groundwater in the contaminated area. Well W13 is located near the centroid of the contaminated zone directly under the area where the plant process liquids penetrated the subsurface. Water from Well P14, located 143 m down gradient in the direction of groundwater flow from Well W13, does not have a hydrocarbon phase but does have a distinct creosote odor. This well penetrates the area of active microbiological activity. Water from Well P119, located 430 m down gradient from Well W13, does not have a distinct creosote odor and is beyond the area of active microbiological activity. The chromatograms of the phenols from samples from Well W13 and those from two laboratory digestors are nearly comparable. The peak heights of the chromatogram of Well P14 are attenuated relative to W13 owing to biodegradation and hydrodynamic dispersion in the groundwater. Phenol, 2-methylphenol, and 3-methylphenol apparently degraded during transport over the 143 m distance from Well W13 to Well P14. This study demonstrated that phenols, a major fraction of coal tar, were degraded in both groundwater and in laboratory digestors with a concomitant production of methane. (Baker-IVI)

The accumulation and chemical forms of cadmium in the zooplankton, Moina macrocopa, were investigated in order to more fully understand the accumulation of cadmium in various steps through the food chain. M. macrocopa were collected and kept in aerated water tanks at 23 C. Cadmium was added to underground water in the tanks at a concentration of 20 micrograms Cd/liter. The animals exposed to cadmium were collected after 0, 24, 48, and 72 hr. Concentrations of cadmium, zinc, and copper were determined. The concentration of cadmium attained a maximum level after 72 hr. At this time the concentrations of zinc and copper were not affected, remaining at control levels. Approximately 60% of the cadmium in the homogenates was extracted into the supernatant fraction and the metal concentration in the supernatants increased with accumulation of the metal in the animals. The cadmium accumulated in M. macrocopa was mainly bound to the low molecular weight cadmium-binding protein whose molecular weight is smaller than that of mammalian metallothioneins. The protein is a mixture of two isoproteins as in the case of malacostracan metallothioneins. (Baker-IVI)

ACCUMULATION OF SEVEN METALS BY CRASSOSTREA GIGAS, CRASSOSTREA MARGARITACEA, PERNA PERNA, AND CHOROMYTILUS MERIDIONALIS,
Port Elizabeth Univ. (South Africa). Dept. of Zoology.
H. R. Watling.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 3, p 317-322, March, 1983. 3 Tab, 18 Ref.

Descriptors: *Mollusks, *Fate of pollutants, *Accumulation, Chromium, Copper, Zinc, Lead, Cadmium, Nickel, Cobalt, Metals.

The accumulation of seven elements by Crassostrea margaritacea, Perna perna and Choromytilus meridionalis was investigated. The rates of accumulation were compared with those achieved by Crassostrea gigas under the same controlled conditions. Experimental solutions containing 100 micrograms/liter of one of the elements were used. The study showed that all seven elements were accumulated to a greater or lesser extent by each of the four species. Exposures lasted 3 weeks. During this period the oysters accumulated zinc and copper at the fastest rates, lead and cadmium at intermediate rates and the remaining elements were accumulated more slowly. Lead is accumulated at the fastest rate by the mussels. Zinc and cadmium in both mussels and copper in P. perna were accumulated at intermediate rates and, as found in the oyster, nickel, cobalt, and chromium were accumulated very slowly. The zinc levels tested were significantly below those already found in many so-called polluted areas. The toxic effect of copper in possibly causing a low mulation rate cannot be discounted. F point of view of indicating metal pollutio marine environment, the tissue-metal conc which is determined for individuals from ed environment must be significantly gre those determined for individuals from an ed area. On the basis of the accumulation f appeared that zinc has not been accumulat these experimental conditions by either o mussels. Moderate accumulation factors h determined for cadmium, copper, nickel, a mium and the very high accumulation fac mated for lead and cobalt suggest that t ments are accumulated very rapidly. It is s that all three species could be used to ind presence of each of these elements in the environment, with the exception of zinc. IVI)

DISTRIBUTION OF POLYCYCLIC AROMATIC HYDROCARBONS IN THE SURFICIAL SEDIMENTS OF CASCO BAY, MAINE,
Bigelow Lab. for Ocean Sciences, West Boothbay Harbor, ME.
P. F. Larsen, D. F. Gadbois, A. C. Johnson, and L. F. Doggett.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 5, p 530-535, May, 1983. 1 Fig, 1 Tab, 10 Ref. NA-80-FA-C-0008.

*Hydrocarbons, *Sediments, *Pollutant identification, Fate of pollutants, Casco Bay, Maine, Carcinogens, Polycyclic aromatic hydrocarbons.

Thirty stations were sampled in Casco Bay in April of 1980 to determine the presence of hydrocarbons in the sediments. Each of the 16 PAH's tested was detected at between 1 and 30 of the test sites. Eight compounds: pyrene, benzo-a-anthracene, chrysene, benzo-b-fluoranthrene, benzo-a-pyrene, dibenzo-a,h-anthracene, benzo-g,h,i-perylene and indeno-1,2,3-c,d-pyrene occurred at over 73% of the stations. All 16 individual PAH's exhibited concentrations in the hundred ppb range at specific points and eight exceeded 1,000 ppb wet weight at least at one station. The highest individual concentration was that of benzo-b-fluoranthene at station 37 which measured 4,500 ppb. Individual stations manifested between 3 and 13 PAH compounds with a mean of 8.57. Total concentrations of PAH at the 30 stations ranged between 215 and 14.425 ppb with a mean of 2.164 ppb. With only one exception stations in the upper and mid sections of the Bay were characterized by values of 900 ppb and below. Concentrations above 2,000 ppb were limited to stations in the vicinity of Portland, including the principal shipping channel into Casco Bay and the mouth of the Presumpscot River. It would seem that a definite possibility exists for the contamination of the living marine resources of this commercially important area. (Baker-IVI)

*Mercury, *Birds, *Fish, *Soil, Spain, Fate of pollutants, Ecosystems, Soil contamination, Heavy metals.

The Parque Nacional de Donana in Spain serves as a winter habitat for migratory birds which breed in Northern Europe. Various levels of mercury were found in the soils of the shore around both the Lucio de Mary Lopez and Lucio del Cangrego Grande lagoons located within the ecosystem. The soil around the Mary Lopez lagoon had a mercury load 2.4 times that at the Cangrego Lagoon. The mean level of mercury in the soil of Mary Lopez lagoon amounts to 0.234 ppm and that at the Cangrego amounts to 0.098 ppm. The average mercury content of the crust of the earth has been calculated at about 0.5 ppm. The rushes growing on the shore of the Mary Lopez lagoon contain 0.41 ppm mercury as opposed to 0.17 ppm in rushes growing on the Cangrego shore. Fish sampled in the Cangrego and Mary Lopez lagoons showed various levels of mercury that appear to increase according to feeding habits. A widespread distribution of mercury was noted from data recorded on birds. Birds of exclusively vegetal feeding showed smaller levels of contamination than those with omnivorous food habits. Only the spoon bill, mostly carnivorous, sampled in the Mary Lopez area showed a 0.87 ppm of total mercury, the highest level found. Eggs showed two different mercury levels according to the food habits of the parents. Duck eggs contained a mean level of 0.07 ppm while those from a more carnivorous bird showed a mean of 0.21 ppm, three times higher. Thus it is evident that mercury occurs in this area of the reserve, but it seems that most of this mercury has a natural origin. (Baker-IVI)

*Fenitrothion, *Absorption, *Soil properties, Phenols, Sediments, 3-Methyl-4-Nitrophenol, Fate of pollutants, Forests, Microbial degradation.

The absorption characteristics of fenitrothion and 3-methyl-4-nitrophenol, its hydrolysis product, on several soils were studied. Four soils and a Lake Superior sediment were used. Both chemicals were adsorbed on sediment and soils in amounts that increased with increasing organic matter content of the adsorbate. Whereas the use of K-values derived from the Freundlich equation has limitations, the use of a modified Freundlich equation presents problems when the slope of the isotherm is appreciably larger than unity. Both compounds can be adsorbed on soils so as to reach concentrations that are fungi-toxic on agar plates. Since compounds adsorbed on soil (and on the organic litter of the forest floor) would not be readily subject to photodegradation, the results of this study indicate that it is necessary to give attention to further studies on the microbial degradation of these compounds. FRACTIONATION OF PHOSPHORUS AND RELEASABLE FRACTION IN SEDIMENT MUD OF OSAKA BAY,
Osaka Prefecture Fisheries Experimental Station (Japan).
H. Joh.
Bulletin of the Japanese Society of Scientific Fisheries, Vol. 49, No. 3, p 447-454, March, 1983. 7 Fig, 11 Ref.

Descriptors: *Phosphates, *Sediments, Bays, Seawater, Path of pollutants, Anaerobic conditions, Osaka Bay, Japan.

This report discusses fractionation of phosphorus in sediment cores of Osaka Bay and the releasable fraction from sediment to sea water in anaerobic condition. Inorganic phosphate in sediment mud was fractionated into four types: soluble-P, Al-P, Fe-P, and Ca-P by the method of Chang et al. Concentrations of Al-P and Fe-P indicate the highest value in 0-5 cm layer except for Al-P in Stn. 4 which is located at the most inner part of the bay. Ca-P contents show relatively high value for each sediment core, ranging from 110 to 190 micro g per g dry mud, but area and vertical variances were not so clear. As Al-P plus Fe-P contents in the sediment increase exponentially with ignition loss; most phosphates which are associated with pollutant substances in the sediment mud are in these two fractions. Three fractions of phosphate: soluble, aluminum and iron phosphate may be released from the sediment in anaerobic condition. It was proved that contents of phosphate released into sea water increased proportionally to those three fraction contents in sediment mud. (Author's abstract)

WETFALL CHEMISTRY STUDIES AROUND A LARGE COAL-FIRED POWER PLANT IN THE SOUTHEASTERN UNITED STATES,
Brookhaven National Lab., Upton, NY. Atmospheric Sciences Div.
A. A. N. Patrinos, M. T. Dana, and R. E. Saylor.
Journal of Geophysical Research, Vol. 88, No. C13, p 8585-8612, October 20, 1983. 22 Fig, 19 Tab, 57 Ref.

Descriptors: *Acid rain, *Air pollution, *Powerplants, Plume washout, Sulfur, Hydrogen ions, Chloride, Sulfur dioxide, Simulation, Chemistry of precipitation, Gas scavenging.

A wetfall chemistry study was conducted within a 15-km radius of a large coal-fired power plant in the southeastern United States. The study was conducted during the winter of 1981 and included event precipitation sampling on a dense network of 31 stations, selected air chemistry monitoring at two sites, and extensive meteorological measurements. The precipitation samples were analyzed for all major inorganic ionic species, including dissolved sulfur dioxide. The meteorological network included a preexisting network of 49 recording rain gages and four surface windsets, the power plant's fully equipped meteorological station, and a bistatic acoustic sounder. This paper presents the results from five of the sampled storms. Plume washout is evident in most target area samples, and sulfur, hydrogen ion, and chloride ion were found to be the predominant plume-related species. Concentrations in the affected regions exceeded the background levels by up to 100% in the case of sulfur and of hydrogen ion, and by up to 145% in the case of chloride ion. Two of the storms were characterized by excess dissolved SO2 amounts in the target samples; for these storms, scavenging model simulations of dissolved SO2 concentrations indicated that deposition of sulfur by SO2 scavenging within 12 km was probably less than 2% of the total emitted. Based on the measured Cl(-) in rainwater, an estimate of the source strength (coal Cl content) using conventional gas scavenging theory appears reasonable. (Author's abstract)

CHARACTERIZATION OF NONVOLATILE AQUEOUS CHLORINATION PRODUCTS OF HUMIC SUBSTANCES,
Massachusetts Univ., Amherst. Dept. of Chemistry.
J. W. Miller, and P. C. Uden.
Environmental Science Technology, Vol. 17, No. 3, p 150-157, March, 1983. 13 Fig, 1 Tab, 28 Ref.

Descriptors: *Chlorinated hydrocarbons, *Chlorination, *Humic acids, Hydrogen ion concentration, Fulvic acid, Chloroform, Dichloroacetic acid, Trichloroacetic acid, Chloral hydrate.

The formation of nonvolatile chloroorganics produced during the aqueous chlorination of humic substances was followed qualitatively and quantitatively. The effects of reaction time, NaOCl to C ratio, pH, and source of humic material were studied with respect to the quantitative formation of chloroform, dichloroacetic acid, trichloroacetic acid, and chloral hydrate. Other gas-chromatographable chloroorganics formed from the chlorination of fulvic acid were produced at levels below these four compounds. Chlorine-selective fingerprint studies were also undertaken to follow the formation of 17 major chlorinated products. (Author's abstract)

MOBILITY IN SOIL AND PLANT AVAILABILITY OF METALS DERIVED FROM INCINERATED MUNICIPAL REFUSE,
Tennessee Valley Authority, Muscle Shoals, AL. Div. of Agricultural Development.
P. M. Giordano, A. D. Behel, Jr., J. E. Lawrence, Jr., J. M. Solleau, and B. N. Bradford.
Environmental Science Technology, Vol. 17, No. 4, p 193-198, April, 1983. 9 Tab, 16 Ref.

Descriptors: *Fly ash, *Leaching, *Heavy metals, Incineration, Municipal wastes, Cadmium, Lead, Chloride, Soil contamination, Waste disposal.

Fly ash residues from several sites in which solid municipal refuse is being incinerated for energy production were found to contain excessive amounts of cadmium and/or lead according to an empirical extraction test (0.5 N acetic acid) developed by the Environmental Protection Agency. Samples of associated bottom ashes contained acceptable levels of Cd and Pb, but several were marginal with respect to Pb content. Leaching tests clearly demonstrated that Cd and, to a lesser extent, Pb were mobile in soil when applied in a fly ash matrix. The high chloride content (10-12%), which is characteristic of these ashes, resulted in metal complexation and enhanced Cd and Pb mobility in soil. Normally these elements are relatively immobile in soils when applied as inorganic salts or contained in municipal sewage sludge. Plant uptake of Cd and Pb in a greenhouse test was marked when fly or finely ground bottom ashes were solid applied. Phytotoxicity of fly ash appeared to be associated with the high salt content rather than with a specific metal. (Author's abstract)

PARTITION EQUILIBRIA OF NONIONIC ORGANIC COMPOUNDS BETWEEN SOIL ORGANIC MATTER AND WATER,
Oregon State Univ., Corvallis. Environmental Health Sciences Center.
C. T. Chiou, P. E. Porter, and D. W. Schmedding.
Environmental Science and Technology, Vol. 17, No. 4, p 227-231, April, 1983. 2 Fig, 1 Tab, 34 Ref. ES-02400, ES-00210, CR-808046.

Descriptors: *Isotherms, *Soil organic matter, *Partition, Organic compounds, Solutes, Sorption, Aromatic compounds, Polymeric humic substances.

Equilibrium isotherms for the simultaneous uptake of binary nonionic organic compounds from water on soil indicated no competitive effect between the two solutes. This observation supports the hypothesis that partition to the soil organic phase is the primary process for sorption of nonionic organic compounds from water on soil. The partition process between soil organic matter and water was analyzed by using the conventional solution concept for solutes in water and the Flory-Huggins treatment for solutes in the polymeric humic phase. Sorption determined for 12 aromatic compounds on a Woodburn soil shows that the extent of solute insolubility in water (S) is the primary factor affecting the soil organic matter-water partition coefficient (Kom) and that the effect of solute incompatibility with soil organic matter is significant but secondary. This explains the commonly observed correlations of log Kom vs. log S and log Kom vs. log Kow (octanol-water). (Author's abstract)

PARTITIONING OF STRONTIUM-90 AMONG AQUEOUS AND MINERAL SPECIES IN A CONTAMINATED AQUIFER,
National Hydrology Research Inst., Ottawa (Ontario).
R. E. Jackson, and K. J. Inch.
Environmental Science Technology, Vol. 17, No. 4, p 231-237, April, 1983. 6 Fig, 3 Tab, 42 Ref.

Descriptors: *Partition, *Strontium radioisotopes, *Groundwater pollution, Groundwater movement, Adsorption, Sand aquifers, Path of pollutants, Vermiculite, Feldspar.

The geochemical partitioning of a toxic metal contaminant, Sr90, during its migration through a shallow sand aquifer is discussed. Adsorption of Sr90 from the contaminated groundwaters (pH about 6, I about 0.001) causes it to have a migration velocity of only 3% of that of transporting groundwater. Five microscopically identified adsorbents were isolated in the aquifer sediments and showed the following affinity sequence for Sr90: vermiculite > feldspar > biotite > muscovite > quartz. While about 80% of the adsorbed Sr90 is exchangeable with 0.1 M SrCl2, the residual adsorbed Sr90 is strongly correlated with extractable Fe, Al, and Mn, suggesting specific adsorption by these metal oxides. An equilibrium adsorption model was used to determine the partitioning of Sr90 between adsorbents and between solid and solution phases. Over 90% of all Sr90 in the aquifer is adsorbed. Approximately 90% of all adsorbed Sr90 is equally divided between vermiculite and feldspar minerals. (Author's abstract)

By means of H:C and O:C atomic ratios tion was obtained on the basic structure, structural changes with varying molecula and origin, of fulvic and humic acids sa various locations of a watershed within t entide provincial park, Quebec. In order t gate also the effect of humification, humi produced by a streptomycete and sampled lar intervals during a 6-month incubatio was included in the investigation. Also stu the effect of ultraviolet irradiation on the of either recently formed or more humifie substances. It was shown that fulvic an acids are more alike in aquatic than in t environments. They are also less aromatic ral waters than in soils and, at least in the fulvic acids, are richer in oxygen. Con what is normally observed for humus from environments, it would appear that for types of humus such as fulvic acids from bial culture, increases in molecular weight degree of humification would result in with a less aromatic character. Humus from natural waters was found to be in advanced state of humification at the summer than at the beginning. Recently fulvic acids appeared to be very sensitive violet irradiation. Organophosphorus pesticides, Hydroly-
n canals, Sediments, Adsorption, Hy-
concentration, Citrus fruits, Florida.

lation of ethion, O,O,O',O'-tetraethyl
ene bis (phosphorodithioate), in irriga-
waters draining a citrus grove in South
urs readily by hydrolysis with a half-
lays. The reaction is pH independent
to 7 with a pseudo-first-order rate
0.0048/day (half-life of 146 days).
7 the reaction is pH dependent with a
order rate constant increasing with
values, suggesting a base-catalyzed hyr-
second-order alkaline hydrolysis rate
.0064/M/day. Half-lives were 62 days
1 day at pH 10. Adsorption to canal sediments was negligible and desorption was rapid because of absence of significant amounts of organic matter. Calculations based upon solubility and vapor pressures of ethion indicate that the rate of evaporative loss is negligible. Ethion did not accumulate in the sediment and water samples from the irrigation canal following spraying, and levels never exceeded 0.017 mg/L in the water or 0.03 micro g/g (dry weight) in the sediments. This suggests that hydrolysis may be a significant mechanism in the loss of ethion from irrigation canal waters in South Florida.

The method most widely adopted and recommended by the ASTM for determination of bromine is an UV spectrophotometric method based on bromide catalysis of iodine oxidation with a working range of 4-100 micrograms/l of bromide. A comparison is offered of this method against an instrumental neutron activation analysis. For unspiked samples the bromide levels obtained by ASTM were markedly lower than the INAA results. The reason for this divergence is that INAA measures total bromine including bromide, bromate and other forms of inorganic bromine as well as non volatile organic bromine, the ASTM method measures principally bromide and bromate. For tap water samples relatively high organic bromine levels are to be expected as significant amounts are produced during chlorination. Inorganic bromine occurs in natural waters principally as bromide although other forms such as bromate and possibly bromite may also be present. Neither the ASTM nor the INAA methods can distinguish between these species of inorganic bromine. An indirect measure of the organic bromine content can be obtained by the difference between INAA and ASTM determinations. For groundwaters bromide concentrations depend principally on the extent of salt water intrusion and the geochemical formation of the aquifer whereas for surface waters factors such as the extent of reuse, the type and quantity of industrial discharge and the potential of other sources of bromine such as road and agricultural runoff are important. IDENTIFICATION OF A MEMBRANE FOULANT IN THE ELECTRODIALYTIC RECOVERY OF NICKEL,
Ford Motor Co., Dearborn, MI. Engineering and Research Staff.
H. C. Heller, and V. Markovac.
Analytical Chemistry, Vol. 55, No. 4, p 551A-557A, April, 1983. 5 Fig, 5 Ref.

Descriptors: *Industrial wastes, *Wastewater treatment, *Membrane processes, Water reuse, Nickel, Electroplating, Electrodialysis, Nickel, Membranes.

Some component present in a nickel plating additive formulation of a major supply company severly and rapidly fouled the membranes during an evaluation of the feasibility of nickel recovery by electrodialysis. Electrodialysis experiments were performed in an electrodialysis stackpack containing anion-selective membranes (103.QZL.219) and cation selective membranes (61.CZL.183). In a solution of identical nickel ion concentration obtained from post plating rinse and therefore containing the additive formulation, the voltage required to maintain 12.5 mA/sq cm in the electrodialysis process rose rapidly from 14 to 40 V in less than 60 min, indicating fouling of the electrodialysis membranes. Attempts to remove the fouling species included filtration through 0.25 micron Millipore filters, adsorption on activated carbon, diatomaceous earth, and polymeric adsorbants; and removal with ion-exchange columns. Ion-exchange columns saturated with foulant could be regenerated to 90% or better of their original capacity by treatment with hydrochloric acid or sodium chloride methanol-water solution. Polyallyl sulfonate was identified as a foulant of the membranes in the electrodialysis of the nickel plating solutions. A separate brightener formulation supplied by a different supplier and containing sodium allyl sulfonate exhibited no fouling. (Baker-IVI)

LAKE ST. CLAIR: SINCE THE MERCURY CRISIS,
Michigan Dept. of Natural Resources, Lansing.
J. H. Hartig.
Water Spectrum, Vol. 15, No. 1, p 19-25, Spring, 1983. 8 Fig.

Descriptors: *Fate of pollutants, *Mercury, *Lakes, *Fish, Lake St. Clair, Detroit River, Public Health, Lake Erie, Industrial wastes, Chemical industry, Regulations, Water pollution control.

In 1969 the mercury crisis in Lake St. Clair was clear. The contamination was arising from the Dow Chemical Chlor-Alkali Plant, in Sarnia, Ontario. Mercury had contaminated both the sediments and the fishery of the St. Clair River and lake, and the Detroit River. Today the monitoring programs have shown a significant decrease of mercury in all species of fish. In general, the concentration of mercury in fish from Lake St. Clair is less than one-third what it was in 1970. The decline of mercury in walleye is particularly significant as walleye are the most sought after sport fish in the lake. The Michigan Department of Public Health has dropped walleye, largemouth bass, smallmouth bass, sheepshead, and white bass from the Lake St. Clair's public health advisory. Only muskellunge are advised to be consumed no more than one meal per week because of elevated mercury levels. The decline has resulted mainly from the cessation of discharge of mercury on the St. Clair River and to the translocation of mercury-containing sediments from Lake St. Clair to Lake Erie. After May of 1970 mercury discharges to the St. Clair River were negligible. Resuspension and onward transportation of mercury containing sediments from Lake St. Clair to Lake Erie has resulted in a 64% decrease in sediment mercury in Lake St. Clair from 1970 to 1974. No major effects were noted in Lake Erie as a result of continued loading of mercury containing sediment from Lake St. Clair, via the Detroit River. The dilution factor in Lake Erie may have been adequate to prevent large-scale uptake of mercury by fishes, or mercury contaminated sediments are being bound and covered up by new sediments. MICROBIAL TRANSFORMATION OF NITROAROMATIC COMPOUNDS IN SEWAGE EFFLUENT,
Cornell Univ. Agricultural Experiment Station, Ithaca, NY. Dept. of Agronomy.
L. E. Hallas, and M. Alexander.
Applied and Environmental Microbiology, Vol. 45, No. 4, p 1234-1241, April, 1983. 7 Fig, 2 Tab, 26 Ref. PHS Training Grant ES-07052.

Descriptors: *Nitroaromatic compounds, *Wastewater, *Effluent, *Microbial degradation, Aromatic compounds, Aerobic conditions, Anaerobic conditions, Metabolism, Benzenes, Fate of pollutants.

The transformation of mono- and dinitroaromatic compounds was measured in sewage effluent maintained under aerobic or anaerobic conditions. Most of the nitrobenzene, 3- and 4-nitrobenzoic acids, and 3- and 4-nitrotoluenes and much of the 1,2- and 1,3-dinitrobenzenes disappeared both in the presence and absence of oxygen. Under anaerobiosis, 2,6-dinitrotoluene and 3,5-dinitrobenzoic acid disappeared slowly, but no loss was evident in 28 days in aerated sewage. Aromatic amines did not

accumulate during the aerobic decomposition of the mononitro compounds. They did appear in nonsterile, but not in sterile, sewage incubated aerobically with the dinitro compounds and anaerobically with all the chemicals. Analysis by gas chromatography and combined gas chromatography-mass spectrometry showed that aniline was formed from nitrobenzene, toluidine was formed from 3- and 4-nitrotoluenes, and aminobenzoic acid was formed from 3- and 4-nitrobenzoic acids under anaerobiosis, and that nitroaniline was formed from 1,2- and 1,3-dinitrobenzenes, aminonitrotoluene resulted from 2,6-dinitrotoluene, and aminonitrobenzoic acid was a product of 3,5-dinitrobenzoic acid under both conditions. The isomeric forms of the metabolites were not established. Aniline, 4-toluidine, and 4-aminobenzoic acid added to sewage disappeared from aerated nonsterile, but not from sterile, sewage or sewage in the absence of oxygen. 2-Nitroaniline, 2-amino-3-nitrotoluene, and 2-amino-5-nitrobenzoic acid added to sewage persisted for at least 60 days in aerobic or anaerobic conditions. Gas chromatographic and gas chromatographic-mass spectrometric analyses demonstrated that acetanilide and 2-methylquinoline were formed from aniline, 4-methylformanilide and 4-methylacetanilide were formed from 4-toluidine, 2-methylbenzimidazole was a product of 2-nitroaniline, and unidentified benzimidazoles were formed from 2-amino-3-nitrotoluene in the absence of oxygen, and that 2-nitroacetanilide and 2-methyl-6-nitroacetanilide were formed from 2-nitroaniline and 2-amino-3-nitrotoluene, respectively, in the presence or absence of oxygen. It is suggested that the transformations of widely used nitroaromatic compounds should be further studied because of the persistence and possible toxicity of products of their metabolism. ENTRAINMENT OF VIRUSES FROM SEPTIC TANK LEACH FIELDS THROUGH A SHALLOW, SANDY SOIL AQUIFER,
Brookhaven National Lab., Upton, NY. Dept. of Energy and Environment.
J. M. Vaughn, E. F. Landry, and M. Z. Thomas.
Applied and Environmental Microbiology, Vol. 45, No. 5, p 1474-1480, May, 1983. 1 Fig, 4 Tab, 25 Ref.

Descriptors: *Wastewater disposal, *Enteroviruses, *Entrainment, Viruses, Aquifers, Water pollution sources, Groundwater pollution, Water quality, Coliforms, Long Island, New York.

Movement of naturally occurring human enteroviruses from a subsurface wastewater disposal system through a shallow aquifer was studied on the south shore of eastern Long Island, New York. The potential for significant entrainment of virus particles was evidenced by their recovery at down-gradient distances of 67.05 m and from aquifer depths of 18 m. The specific limits of virus entrainment through the system could not be determined, as wells had not been installed beyond 67 m down-gradient of deeper than 18 m. A significant negative correlation was observed between virus occurrence and the distance from the 'septage' (leaching pool) source. Virus occurrence could not be statistically correlated with either total or fecal coliforms, indicating the limitations of current microbial water quality indicators for predicting virological quality of groundwater. LONGEVITY OF SALMONELLA TYPHIMURIUM IN TILAPIA AUREA AND WATER FROM POOLS FERTILIZED WITH SWINE WASTE,
Auburn Univ., AL. Dept. of Fisheries and Allied Aquacultures.
D. A. Baker, R. O. Smitherman, and T. A. McCaskey
Applied and Environmental Microbiology, Vol. 45, No. 5, p 1548-1554, May, 1983. 3 Fig, 3 Tab, 53 Ref

Descriptors: *Salmonella, *Wastewater aquaculture, *Aquaculture, *Tilapia, Public health, Wastewater disposal, Animal wastes, Bacteria.

Salmonella contamination is a potential public health concern in wastewater aquaculture, because humans and farm animals may shed salmonellae intermittently in their feces. Thus, fish being cultured in wastewater might come in contact with salmonellae. Field studies were conducted during the spring and summer of 1980 using 14 8,000 liter pools stocked with Tilapia aurea. Salmonella typhimurium declined rapidly when inoculated into T. aurea culture pools fertilized with fresh swine waste. Within the water column, a 95% decline of viable cells occurred during the first 6 h. Isolation of viable salmonellae was possible at 16 days post-inoculation, but not at 32 days. Similarly, salmonellae could be detected in the viscera and epithelium of T. aurea at 16 days, although not at 32 days. Salmonellae were not isolated from the fish flesh, nor was there evidence of septicemic infection. (Moore-IVI)

SEASONAL VARIATION IN SURVIVAL OF ESCHERICHIA COLI EXPOSED IN SITU IN MEMBRANE DIFFUSION CHAMBERS CONTAINING FILTERED AND NONFILTERED ESTUARINE WATER,
Virginia Inst. of Marine Science, Gloucester Point. Dept. of Estuarine and Coastal Ecology.
I. C. Anderson, M. W. Rhodes, and H. I. Kator.
Applied and Environmental Microbiology, Vol. 45, No. 6, p 1877-1883, June, 1983. 4 Fig, 43 Ref.

Descriptors: *Escherichia coli, *Estuarine environment, *Water temperature, Bacteria, Microorganisms, Public health, Water quality.

Human fecal Escherichia coli isolates were exposed over a seasonal cycle to estuarine water in diffusion chambers filled with double-filtered (0.45 and 0.2 micro m) and nonfiltered water. Laboratory manipulations of E. coli cultures before estuarine exposure were reduced to minimize sublethal stress, and nonselective or resuscitative enumeration techniques were employed to maximize recovery of stressed cells. E. coli was capable of extended survival during in situ exposure to estuarine water, provided eucaryotes were excluded from diffusion chambers. Survival was directly related to temperature in absence of the eucaryote component of the natural microbiota. Although it was not possible to prevent eventual bacterial contamination in double-filtered water, there was no direct evidence that such contamination affected E. coli survival. Conversely, E. coli disapparance was most pronounced at warmer temperatures in the presence of the natural microbiota, and decline coincided with increasing eucaryote densities. In contrast, the decline of E. coli during winter was similar in both filtered and nonfiltered seawater. (Author's abstract)

ENVIRONMENTAL EFFECTS OF IN SITU COAL GASIFICATION,
Wyoming Univ., Laramie. Dept. of Civil Engineering.
M. J. Humenick, T. F. Edgar, and R. J. Charbeneau.
AICHE Symposium Series, Vol. 79, No. 226, p 139-153, 1983. 2 Fig, 6 Tab, 54 Ref.

Descriptors: *Coal gasification, *Water pollution sources, Organic compounds, Phenols, Gasification, Fate of pollutants, Surface waters, Groundwater pollution, Environmental effects.

This review evaluates the environmental impact of underground coal gasification. Documentation projects that pollutants are released to groundwaters when normal flow returns to a postgasification zone. During the gasification phase, the high temperature gases produced can migrate into surrounding strata, where cooling occurs with attendant condensation or deposition of various chemical compounds. The bulk of the condensed materials are organic compounds including light hydrocarbons, phenols, oils, and tars. After gasification is completed, an ash residue remains in the burn cavity which yields soluble inorganic compounds to reinvading groundwaters. Wastewaters generated above the ground arise principally from the gas cooling step, which causes condensation of oils, and tars from the gas generated in si condensate may contain three phases - wa and solids. The water phase can contain hi centrations of phenols and other organi pounds, ammonia, hydrogen sulfide, carbo ide and various inorganic compounds (Bak W84-01662

WATER QUALITY MONITORING AT HOE CREEK TEST SITE: REVIEW AND LIMINARY CONCLUSIONS,

IDENTIFICATION OF ORGANIC COMPOUNDS IN LEACHATE FROM A WASTE TIP,
Instituut voor Cultuurtechniek en Waterhuishouding, Wageningen (Netherlands).
J. Harmsen.
Water Resources, Vol. 17, No. 6, p 699-705, June, 1983. 5 Fig, 3 Tab, 9 Ref.

Descriptors: *Leachates, *Organic compounds, *Waste dumps, Heavy metals, Amines, Alcohols, Hydrocarbons, Esters, Terpenes, Phthalates, Fermentation, Pollutant identification.

The first type of leachate was collected from a municipal waste dump (tip) in the acidification stage. The organic load of this leachate was high and consisted mainly of free volatile acids, over 95% of the total organic carbon (TOC). Volatile amines and ethanol were also present (0.8 and 0.7% of the TOC respectively). The leachate was extracted with hexane and the extract was analyzed with infrared and nuclear magnetic resonance spectroscopy and a gas chromatograph-mass spectrometer combination. In the extract alcohols, hydrocarbons, esters, terpenes and phthalates were identified. High molecular weight compounds were present only in a low concentration. The second type of leachate was collected from a waste dump in the methane fermentation stage. The organic load was relatively low. An important part of the organics was identified as high molecular weight compounds. About 32% of the organic carbon consisted of compounds with a molecular weight over 1000. Acids, amines and alcohols were not detected. The organic compounds present were end products of degradation processes. There was a remarkable difference in heavy metal content between the two types of leachate. During the acidification stage, metals are more soluble because of the lower pH and by complexation with the free volatile acids. In the methane fermentation stage, the acids dissappear, the pH rises and there is only a relatively small amount of organic compounds left, which results in a drastic fall in the metal concentrations, except for lead. MIGRATION OF CONTAMINANTS IN GROUNDWATER AT A LANDFILL: A CASE STUDY; 1. GROUNDWATER FLOW AND PLUME DELINEATION,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
D. S. MacFarlane, J. A. Cherry, R. W. Gillham, and E. A. Sudicky.
Journal of Hydrology, Vol. 63, No. 1-2, p 1-29, May, 1983. 9 Fig, 1 Tab, 31 Ref.

Descriptors: *Pollutant migration, *Groundwater pollution, *Landfills, *Leachates, Chloride, Sulfate, Conductance, Water temperature, Water table mounding, Permeability coefficient, Groundwater movement, Plumes, Groundwater recharge, Mixing, Dispersion.

A landfill-derived contaminant plume with a maximum width of 600 m, a length of 700 m and a maximum depth of 20 m in an unconfined sand aquifer was delineated by means of a monitoring network that includes standpipe piezometers, multilevel point-samplers and bundle-piezometers. The extent of detectable contamination caused by the landfill, which began operation in 1940 and which became inactive in 1976, was determined from the distributions of chloride, sulfate and electrical conductance in the sand aquifer, all of which have levels in the leachate that are greatly above those in uncontaminated groundwater. The maximum temperature of groundwater in the zone of contamination beneath the landfill is 12 C, which is 4-5 C above background. The thermal plume in the aquifer extends 150 m downgradient from the center of the landfill. A slight transient water table mound exists beneath the landfill in the late spring and summer in response to snowmelt and heavy rainfall. Beneath the landfill, the zone of leachate contamination extends to the bottom of the aquifer, apparently because of transient downward components to hydraulic gradient caused by the water-table mound and possibly because of the higher density and lower viscosity of the contaminated water. Values of hydraulic conductivity, which show variations due to local heterogeneity, were obtained from slug tests of piezometers, from pumping tests and from laboratory tests. Because of the inherent uncertainty in the aquifer parameter values, the 38-yr. frontal position of the plume calculated using the Darcy equation with the assumption of plug flow can differ from the observed frontal position by many hundreds of meters, although the use of mean parameter values produces a close agreement. The width of the plume is large relative to the width of the landfill and can be accounted for primarily by variable periods of lateral east- and westward flow caused by changes in water-table configuration due to the variable nature of recharge. Northward from the landfill, the vertical thickness of the plume decreases and the top of the plume is farther below the water table. The thickness of the zone of uncontaminated water downflow from the landfill increases. Because dispersion in the vertical direction is weak, there is very little mixing between the overlying zone of recharge water and the contaminant plume. Concentration profiles are irregular beneath and near the landfill and become smooth downgradient where the maximum concentrations are much less than those beneath the landfill. These features are attributed to a strong influence of longitudinal dispersion. The plume passes beneath a small shallow stream near the landfill without significant influence on the stream. (Author's abstract)

MIGRATION OF CONTAMINANTS IN GROUNDWATER AT A LANDFILL: A CASE STUDY; 2. GROUNDWATER MONITORING DEVICES,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
J. A. Cherry, R. W. Gillham, E. G. Anderson, and P. E. Johnson.
Journal of Hydrology, Vol. 63, No. 1-2, p 31-49, May, 1983. 5 Fig, 13 Ref.

Descriptors: *Groundwater pollution, *Monitoring, *Sampling, Plumes, Piezometers, Landfills, Leachates, Water quality, Water table, Sand aquifers, Networks.

Six types of devices for groundwater monitoring were used on an experimental basis in the investigation of the plume of contamination in the unconfined sandy aquifer at the Borden landfill. These include: standpipe piezometers, water-table standpipes, an augerhead sampler, suction-type and positive-displacement-type multilevel point-samplers, and bundle-piezometers. With the exception of the first two, each of these devices provides a means of obtaining vertical sample profiles of groundwater from a single borehole. The auger-head sampler, which is a device that is attached to the cutting head of conventional continuous-flight hollow-stem augers, yields samples from relatively undistributed aquifer zones as the augers are advanced downward in the borehole from one depth of sampling to another. This method is a rapid means of acquiring water-quality profiles for mapping the distribution of a contaminant plume. The other three profiling devices can be used to establish permanent networks for groundwater-quality monitoring. A suction-type multilevel sampler consists of twenty or more narrow polyethylene or polypropylene tubes contained in a PVC casing that is capped at the bottom. Each tube extends to a different depth and is attached to a small screened sampling point that extends through the casing to draw water from the aquifer when suction is applied. A positive-displacement multilevel sompler is similar except that each sampling point is connected to a positive-displacement pumping device located inside the PVC casing adjacent to the screen. Use of the suction-type multilevel sampler is limited to zones where the water table is less than the suction-lift depth of 8 or 9 m. The positive-displacement sampler can be used even if the water table is at a much greater depth. A bundle-piezometer consists of 1.2-cm O.D. flexible polyethylene tubes, each with a short screened section at the bottom, fastened as a bundle around a semi-rigid center-piezometer constructed of thick-walled 2-cm O.D. PVC pipe. In shallow water-table areas water is withdrawn from each of the tubes and from the PVC piezometer by suction. In areas with a deep water table, samples are obtained

by bailing with a narrow tube with a check valve on the bottom or by displacement using a double- or triple-tube gas-drive sampler. The positive-displacement multilevel sampler or use of the gas-drive samplers in the bundle-piezometers provide the best opportunities for collecting samples that can be filtered and have preservatives added without the water being influenced excessively. Networks of these three types of devices for multilevel groundwater monitoring were installed in the Borden aquifer of means of hollow-stem augers. The devices are particularly well suited for use in aquifers composed of cohesionless sand or gravel that have little or no clay and groundwater flow that is primarily horizontal. When 8-cm diameter hollow-stem augers are used, as many as eight polyethylene tubes are included conveniently in each bundle-piezometer. If augers with a large hollow-stem are used, more tubes can be assembled in each bundle. (Author's abstract)
W84-01685

MIGRATION OF CONTAMINANTS IN GROUNDWATER AT A LANDFILL: A CASE STUDY; 3. TRITIUM AS AN INDICATOR OF DISPERSION AND RECHARGE,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
B. C. E. Egboka, J. A. Cherry, R. N. Farvolden, and E. O. Frind.
Journal of Hydrology, Vol. 63, No. 1-2, p 51-80, May, 1983. 10 Fig, 34 Ref.

Descriptors: *Groundwater movement, *Tritium, *Tracers, Groundwater pollution, Plumes, Landfills, Leachate, Radioactive tracers, Chloride, Sulfate, Hydrodynamic dispersion, Precipitation, Mixing, Simulation.

Tritium serves as an identifier or tracer of post-1952 water in groundwater flow systems, because major atmospheric testing of nuclear weapons began in 1953. The distribution of 3H in and near the contaminant plume at the Borden landfill was determined by analysis of samples from multilevel point-samplers and from bundle-piezometers. The contaminant plume, which was delineated using Cl(-) and SO4(2-) patterns, was found to contain a large zone of tritiated water and a small zone with no detectable H3. Landfilling operations at the site began in 1940, and as the plume developed in the period from 1940 to 1952, any natural H3 that may have existed in the plume during this period is now below the detection level. During the years in the 1960's in which peak H3 concentrations occurred, values of thousands of tritium units (TU) in precipitation were common and levels of many hundreds of TU or higher existed almost continuously. In the zone of tritiated water in the plume and in the tritiated zone in the natural groundwater up- and downgradient of the plume, all of the sample points except three in the plume had concentrations below 150 TU. Two of these three have concentrations below 290 TU. The general occurrence in the aquifer of H3 levels that are much below the high levels that existed in precipitation prior to the 1970's is attributed to radioactive decay and to the effect of longitudinal hydrodynamic dispersion that has caused mixing of the tritiated groundwater with older untritiated water. Simulated H3 distributions using longitudinal dispersivity values in the range of 30-60 m gave H3 distributions similar to the field values. The strong longitudinal dispersion is believed to be caused by mixing between the ubiquitous layers of fine- and medium-grained sand and silty sand that comprise the aquifer. An estimate of the average annual rate of recharge that has contributed to the groundwater zone beneath the landfill during the bomb-tritium period was obtained by comparing the input of H3 to an area segment of the landfill with the H3 contained within a groundwater flow tube leading from the specified area along the centerline of the contaminant plume. This approach yielded a minimum average annual recharge rate of approximately 50%, with the main cause of uncertainty being the extent of the area in which recharge occurs. (Moore-IVI)

MIGRATION OF CONTAMINANTS IN GROUNDWATER AT A LANDFILL: A CASE STUDY; 4. A NATURAL-GRADIENT DISPERSION TEST,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
E. A. Sudicky, J. A. Cherry, and E. O. Frind.
Journal of Hydrology, Vol. 63, No. 1-2, p 81-108, May, 1983. 15 Fig, 3 Tab, 26 Ref.

Descriptors: *Groundwater movement, *Tracers, *Dispersion, Landfill, Leachates, Chlorides, Path of pollutants, Groundwater pollution, Simulation, Hydraulic gradient.

A natural-gradient tracer test using a chloride solution with an initial injection volume of 0.7 cu m was performed in the sandy aquifer at the Borden site. The solution was injected into five well points set about 1 m below the water table in an uncontaminated zone situated above the contaminant plume at a location 450 m downflow from the landfill. Soon after injection, the tracer slug gradually split into two halves, one half moving horizontally at an average velocity of 0.0000029 m/s and the other horizontally at 0.00000082 m/s. Although the split has been attributed to local lateral heterogeneity, the nature of the heterogeneity and its influence on the hydraulic-head distribution were not clearly distinguishable in the field data obtained before, during and after the test. The chloride patterns for each of the two halves of the tracer slug evolved into Gaussian forms although the patterns demonstrated some irregularity at early time. The relatively smooth Gaussian forms were unexpected because the aquifer has numerous small-scale heterogeneities observed in vertical cores obtained from the tracer zone and because the glaciofluvial origin of the aquifer suggests that heterogeneities are not laterally continuous. Simulated chloride distributions from a three-dimensional analytical solution to the advection-dispersion equation were fitted to the field data to obtain best-fit estimates of the values of longitudinal, transverse-horizontal and transverse-vertical dispersivity at various travel distances for each of the two halves of the tracer zone. This is the first known field test that has permitted the estimation of three principal dispersion coefficients in layered media. The longitudinal dispersivity was found to increase from 0.01 m at a distance of 0.75 m from the source to 0.08 m at 11.0 m. The transverse-horizontal dispersivity increased also to a value of 0.03 m at 11.0 m. Transverse-vertical dispersion was very weak and was accounted for by molecular diffusion. The relative lack of vertical dispersion is consistent with the shape of the plume of leachate contamination from the landfill. The observed increase in dispersivity along the path of migration is likely caused by heterogeneities. (Moore-IVI)

MIGRATION OF CONTAMINANTS IN GROUNDWATER AT A LANDFILL: A CASE STUDY; 5. CATION MIGRATION IN THE DISPERSION TEST,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
J. T. Dance, and E. J. Reardon.
Journal of Hydrology, Vol. 63, No. 1-2, p 109-130, May, 1983. 12 Fig, 3 Tab, 16 Ref.

Descriptors: *Groundwater movement, *Tracers, *Path of pollutants, Calcium, Magnesium, Sodium, Potassium, Groundwater pollution, Landfill, Leachate, Model studies, Dispersion.

A shallow natural-gradient tracer test was conducted in an unconfined sandy aquifer at the Borden landfill site in June 1978. The tracer injected was a chloride solution containing approximately equimolar concentrations of the major cations at levels significantly above those in the background groundwater. Samples collected during monitoring of the tracer were analyzed for calcium, magnesium, sodium and potassium. The results showed an order of attenuation for major cations of K > Mg > Na. Ca, which was the dominant species on the exchange sites before injection of the tracer solution, was liberated during flow of the solution, resulting in the development of a calcium halo at the leading edge of the tracer solution. A one-dimensional mixing-cell model was used to simulate the results of the injection experiment. Both the field and model results show that the chemical composition of the background groundwater is changed due to exchange reactions as it flo

Least squares regression and linear programming for least absolute error estimation are each combined with groundwater solute transport simulation to identify the locations and magnitudes of aquifer pollutant sources. Pollutant sources are identified by matching simulated and measured nonreacting solute concentration data. Known hydraulic parameters are assumed, but concentration data errors are considered explicitly. The identification models are demonstrated and compared using two hypothetical aquifer systems, one for the steady state case and the other for the transient case. Steady state models identified unknown pipe leak locations and the leak magnitudes based upon sparse and spatially distributed chloride and tritium data. The number of likely leak locations was restricted in the models by employing mixed integer programming and stepwise multiple regression. Transient models identified several annual disposal fluxes in the aquifer based upon concentration histories collected at observation wells. Conservative solute concentration data were abundant and contained substantial errors. Minimizing either least absolute or least squared errors was successful in identifying pollutant sources. Error analysis is demonstrated for the results given by either method. (Moore-IVI)

Selected chemical substances (simazine, lindane, tri-, tetrachloroethene) were fed into an artificial aquifer (100 m) operated with diluted seepage water from an aerobic landfill. Numerous sampling points made it possible to obtain more information about a three-dimensional distribution of the substances within the aquifer. Elimination and retention can be observed as well. Problems of sampling and analytical procedures are discussed. It was obvious that the methods of sampling and determination required certain adaptions because of the difficult local conditions and the complex matrix composition, respectively. The work was carried out within the scope of an interdisciplinary research program. (Author's abstract)

SLAKING MODES OF GEOLOGIC MATERIALS AND THEIR IMPACT ON EMBANKMENT STABILIZATION,
E. F. Perry, and D. E. Andrews.
Transportation Research Record, Vol. 873, p 22-28, 1982. 3 Fig, 2 Tab, 5 Ref.

Descriptors: *Mine wastes, *Spoil banks, *Slaking, Infiltration, Sheet erosion, Water pollution sources, Appalachian Basin.

The results of a study of the impacts of slaking on surface mine spoils in the Appalachian Basin are discussed. Representative samples were collected for laboratory analyses from core borings near the active highwall and from test pits excavated in fresh and 2-, 5-, and 10-year-old spoils from four selected mine sites. Extensive qualitative and semiquantitative data were collected on the behavior, causes, and effect of slaking materials. Three slaking models were identified in the field: (a) slaking to constituent grain size; (b) chip slaking to thin, platy fragments; and (c) slab or block slaking to large, approximately equidimensional fragments. These modes are dependent on inherent material properties such as bedding, cementation, and grain size and may affect overall spoil pile or embankment stability. Slaking to inherent grain size promoted surface crusting, reducing infiltration and accelerating sheet erosion. Stability problems in embankments and spoil piles can be anticipated by observing the rate, degree, and modes of slaking. (Author's abstract)

DYNAMIC ADVECTIVE WATER QUALITY MODEL FOR RIVERS,
Ohio State Univ., Columbus. Dept. of Civil Engineering.
K. W. Bedford, R. M. Sykes, and C. Libicki.
Journal of Environmental Engineering, Vol. 109, No. 3, p 535-554, June, 1983. 5 Fig, 2 Tab, 34 Ref.

Descriptors: *Water quality, *Storm runoff, *Mathematical models, Hydrodynamics, Plankton, Sedimentation, Diffusion, Light effects, Turbulence, Biochemical oxygen demand, Nitrogen, Orthophosphate, Olentangy River, Ohio.

A dynamic water quality model for storm induced flows in rivers is presented. The hydrodynamic portion is solved by a four-point implicit Newton-Raphson procedure, while the water quality code is formulated with a Holley-Preissmann nonlinear formulation. The water quality model represents the effects of biodegradation by plankton, sedimentation, and diffusion of material into the benthos by a single turbulence dependent decay term. Eight constituents are employed and the effects of light shading are considered. Two simple tests were used to provide simple initial calibrations. The first test, the propagation of a Gaussian wave, demonstrated the necessity of higher order treatment of the water quality numerical analog. The second test was a steady state test of the water quality model against data from the Olentangy River. The minimum kinetic structure required for Ohio streams should include CBOD, organic nitrogen, ammonia nitrigen, nitrate nitrogen, and orthophosphate. (Author's abstract)

ACID RAIN MODEL: CANOPY MODULE,
Tetra Tech, Inc., Lafayette, CA.
C. W. Chen, R. J. M. Hudson, S. A. Gherini, J. D. Dean, and R. A. Goldstein.
Journal of Environmental Engineering, Vol. 109, No. 3, p 585-603, June, 1983. 4 Fig, 7 Tab, 31 Ref.

Descriptors: *Acid rain, *Canopy, *Water pollution sources, Throughfall, Dry deposition, Forest watersheds, Nitrification, Oxidation, Acidity, Particulates, Air quality, Woods Lake, New York.

As a part of the Integrated Lake-watershed Acidification Study, and acid rain model is being developed to provide quantitative linkage between acid deposition and lake acidification. A canopy model has been developed to calculate throughfall characteristics based on canopy properties, ambient air quality, and precipitation quantity and quality. The processes considered include wet and dry deposition, leaf exudation, nitrification, and oxidation of SO2 and NOx. The canopy model requires only standard input data that can be obtained by use of rain gages, thermometers, dry and wet collectors. The model has been calibrated with data collected at Woods Lake in the Adirondack Mountains of New York. The model has accurately simulated throughfall volume and the concentration of 15 throughfall chemical constituents. Ammonium, NH4(+) accumulated on the canopy is nitrified rapidly, resulting in an increase in acidity and nitrate fluxes. The dominant process occurring in

the coniferous canopy is dry deposition. Calculations suggest that dry deposition measured by bulk collectors grossly underestimates the total amount of dry deposition to the forested watershed. The enrichment of acidity in coniferous throughfall is derived primarily from the accumulation of acidic air particulates. The dominant process occurring in the deciduous canopy is exudation. This partially neutralizes the acidic deposition. (Moore-IVI)

5C. Effects Of Pollution

EFFECTS OF CRUDE OIL AND NAPHTHALENE ON GROWTH, CALORIC CONTENT, AND FAT CONTENT OF PINK SALMON JUVENILES IN SEAWATER,
National Marine Fisheries Service, Auke Bay, AK. Auke Bay Lab.
A. Moles, and S. D. Rice.
Transactions of the American Fisheries Society, Vol. 112, No. 2A, p 205-211, March, 1983. 1 Fig, 4 Tab, 22 Ref.

Descriptors: *Salmon, *Toxicity, *Oil, *Hydrocarbons, Growth, Juvenile growth stages, Naphthalene, Water pollution effects.

Juvenile pink salmon Oncorhynchus gorbuscha were exposed for 40 days to stable, sublethal concentrations of naphthalene (<0.80 mg/liter) and the water-soluble fraction of Cook Inlet crude oil (<0.87 mg/liter total aromatic hydrocarbons). All fish were fed equal daily rations of Oregon Moist Pellet Formula II. Concentrations (percentage of the 96-hour LC50, median lethal concentration) of 10% naphthalene and 14% water-soluble fraction of crude oil did not affect wet weight or length of exposed fish. At higher concentrations, however, growth per day determined from wet weight decreased with increased toxicant concentrations. Change in length of the fish was not a sensitive measure of toxicity. Fish exposed for 40 days to concentrations of toxicants as low as 33% of the 96-hour LC50 weighed significantly less than control fish ($P<0.05$). Juveniles exposed to the water-soluble fraction of crude oil had slower growth rates than those exposed to the same concentration (percentage of the LC50) of naphthalene. Fish exposed to either naphthalene or the the water-soluble fraction of crude oil had decreased caloric content; however, fat content of the fish was not affected. Chronic marine oil pollution at a concentration as low as 0.40 mg/liter total aromatic hydrocarbons could reduce growth of juvenile pink salmon. (Author's abstract)

SIMULATION OF STRIPED BASS EGG AND LARVA DEVELOPMENT BASED ON TEMPERATURE,
National Marine Fisheries Service, Woods Hole, MA. Northeast Fisheries Center.
J. Boreman.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 286-292, March, 1983. 4 Fig, 1 Tab, 23 Ref.

Descriptors: *Water temperature, *Bass, Fish eggs, Larvae, Mortality, Simulation, Growth, Mathematical models, Hudson River.

Comparisons of simulated and observed egg and larva abundance patterns for Hudson River striped bass Morone saxatilis during 1975 and 1976 provided support for a previously stated hypothesis that a sudden drop in water temperature during late May 1976 was associated with almost complete disappearance of cohorts spawned before that date. The major period of mortality for the earlier-spawned cohorts may have occurred during or immediately following egg hatching rather than immediately following yolk absorption as had been previously postulated. (Author's abstract)

COMPARATIVE TEMPERATURE-DEPENDENT GROWTH RATES OF LARGEMOUTH AND SMALLMOUTH BASS FRY,
Oak Ridge National Lab., TN. Environmental Sciences Div.
C. C. Coutant, and D. L. DeAngelis.
Transactions of the American Fisheries Society, Vol. 112, No. 3, p 416-423, May, 1983. 2 Fig, 1 Tab, 20 Ref. W-7405-eng-26.

Descriptors: *Bass, *Growth, *Water temperature, Juvenile growth stages, Predation.

First-month growth was temperature-dependent for fry of largemouth bass Micropterus salmoides and smallmouth bass M. dolomieui that were raised simultaneously under identical conditions. Similar temperatures (25-27 C) produced the fastest growth rates in both species, although largemouth bass grew most rapidly at the higher end of this range. Largemouth bass generally grew faster than smallmouth bass, particularly in the 25 to 30 C range (average 1.4 times). Variance about the mean standard length increased at higher temperatures. Differing temperature-dependent growth rates and size distributions for the two species may influence their relative abilities to survive predation and to form strong year classes in temperature regimes that differ due to latitude or weather. RELATIONSHIP BETWEEN OPTIMUM TEMPERATURES FOR GROWTH AND PREFERRED TEMPERATURES FOR THE YOUNG OF FOUR FISH SPECIES,
Ecological Analysts, Inc., Sparks, MD.
R. L. Kellogg, and J. J. Gift.
Transactions of the American Fisheries Society, Vol. 112, No. 3, p 424-430, May, 1983. 1 Fig, 3 Tab, 10 Ref.

Descriptors: *Fish behavior, *Water temperature, *Growth, Bass, Perch, Catfish, Shiner, Thermoregulation.

Optimum temperatures for growth and temperature preference were estimated and compared for young striped bass Morone saxatilis, white perch Morone americana, white catfish Ictalurus catus, and spottail shiner Notropis hudsonius to determine how closely behavioral thermoregulation corresponded to optimal growth temperatures. Differences between the final preferenda and the optimum growth temperatures were less than 2 C. The percentage of preferred temperatures that were within the temperature range corresponding to 75-100% of maximum growth was 76-100%. Only a small percentage (0.17%) of preferred temperatures were greater than the upper limit of the range supporting 75% or more of maximum growth, indicating that fish were avoiding temperatures that were suboptimal for prolonged exposures. TOXICITY OF TEXAN PETROLEUM WELL BRINE TO THE SHEEPSHEAD MINNOW (CYPRINODON VARIEGATUS), A COMMON ESTUARINE FISH,
Fish and Wildlife Service, Victoria, TX.
J. K. Andreasen, and R. W. Spears.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 3, p 277-283, March, 1983. 1 Fig, 1 Tab, 16 Ref.

Descriptors: *Environmental effects, *Brines, Water pollution effects, Saline water, Industrial wastes, Oil industry, Fish, Toxicity, Minnows, Estuaries.

A series of tests was conducted including tolerance testing with artificial sea salts and with petroleum brine in two different dilution waters. The 96 hr LC50 for sheepshead minnows exposed to artificial seasalt was 60 0/00. The 96 hr LC50 for petroleum brine diluted with deionized water was 35 0/00. This salinity occurred when the test water consisted of about 55% brine. For brine diluted with seawater the LC50 was 52 0/00 or 60% dilution. Analysis of test water showed that concentrations of calcium and manganese were much higher and the concentrations of sulfate was lower in petroleum brine diluted with either deionized water or seawater than in normal seawater. While s
head minnows are hardy in their tolerance o
ity, petroleum brine differs from normal se
in the relative concentration of various ion
results of these tests showed that laboratory
leum brines are acutely toxic to sheepshea
nows when diluted about 40% with seawate
salinity of 52 0/00. Petroleum brine mixed
with seawater to a salinity of 37 0/00 was a
toxic to white and brown shrimp. The toxic
petroleum brine in a natural situation is deter
by the amount of brine being discharged, th
ciency of the brine/oil separator, the volume
receiving water, and the rate at which mixin
exchange take place. Reductions in the fresh
inflow to Texas estuaries or increases in
discharge will increase the probability of
conditions being created in some estuarine sy

ATION OF CHANNEL CATFISH (IC-
S PUNCTATUS) TO NITRATE,
ker, and T. E. Schwedler.
of Environmental Contamination and
gy, Vol. 30, No. 5, p 516-521, May, 1983.

Nitrates, *Acclimatization, Methemoglo-
sh, Channel catfish, Water quality, Water
effects, Lakes, Ponds, Fish behavior, Fish
Fish stocking, Chlorides.

bility that channel catfish can acclimate
was studied. In tests with fish that had
ously been exposed to more than 0.01
fish developed higher levels of methe-
than fish with an immediate past history
re to relatively high NO2(-)/Cl(-) ratios.
el catfish fingerlings (45 g average
ot previously exposed, the percent meth-
ı decreased during the study period as
);Cl(-) molar ratio decreased. Within one
being stocked into a pond containing
0 fingerlings that had been exposed to
ncentrations than 3.0 mg/l NO2(-)-N for
ıe preceding two weeks and where the
inity was 277 mg/liter as CaCO3, methe-
values had increased to 56%. For at least
the unacclimated fish has percent methe-
values more than twice as high as accli-
ı, with levels not decreasing to compara-
until 15 days after stocking. In another
t, the mean methemoglobin in fish re-
single dose of 3.28 mg/l NO2(-)-N was
h higher than the predicted value of 39%
globin. The findings could have implica-
both research and commercial culture
agement. In west central Mississippi ni-
uced methemoglobinemia is currently
by adding a chloride salt to decrease the
(-) molar ratio to 0.25. This results in
globin levels between 25 and 30%, and is
to prevent death of fish in the pond.
if the pond is stocked with fish previous-
sed to high NO2(-)/Cl(-) molar ratios the
ish may develop methemoglobin levels
her than the indigenous population and
ing severe methemoglobinemia in the
sh may result in death or stress, particu-
solved oxygen levels are marginally low.

pollution effects, Minnows.

ninnows were used to determine which
l organs were affected by acute exposure to the water soluble fraction (WSF) of JP-4, an aviation fuel derived from petroleum. The only lesions strongly implicated as being caused by exposure to WSF JP-4 were degeneration and necrosis of segments of the mucosa covering the olfactory rosette. A low incidence of cellular alterations was found in the pseudobranch and gill of exposed fish suggesting possible toxicant related effect. Degeneration and necrosis of the nasal mucosa were absent in the control and 10 dose groups, but were present in 50% of the group exposed to 10 mg/l WSF JP-4 and these lesions were seen in high-dose subjects as early as six hours after exposure. Affected segments of the mucosa often appeared only slightly thickened. Focal cellular alterations were noted in acidophilic cells of the pseudobranch in about 1/4 of the fish exposed to 5 and 10 mg/l WSF JP-4. These alterations included acute cellular swelling, cytoplasmic vacuolization, and cytoplasmic inclusions. Other microscopic observations of low incidence in control and exposed fish that were not considered to be related included the following: choroiditis of the eye, granulomatous thyjitis, and hepatocellular cytoplasmic vacuolar changes. EFFECT OF CALCIUM AND ALUMINUM CONCENTRATIONS ON THE SURVIVAL OF BROWN TROUT (SALMO TRUTTA) AT LOW PH,
Central Electricity Generating Board, Ratcliffe-on-Soar (England). Freshwater Biology Unit.
D. J. A. Brown.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 5, p 582-587, May, 1983.

*Calcium, *Aluminum, *Trout, *Survival, Acidity, Fish, Water pollution effects, Toxicity.

Survival times of yolk sac fry of brown trout were determined at various levels of pH and at different concentrations of calcium and aluminum solutions. In the absence of aluminum, mortalities occurred at pH 4.5 only with 0.25 and 0.5 mg/l of calcium. In solutions containing 0.25 mg/l of aluminum, however, a complete range of responses was noted, from no or very low survival with 0.5 mg/l calcium to almost complete survival with 2.0 mg/l of calcium. Solutions containing 0.5 mg/l of aluminum lead to almost complete mortalities with calcium concentrations of 0.25 and 0.5 mg/l and still significant mortalities at higher calcium concentrations. There is a tendence for higher pHs to be more toxic especially in solutions containing 0.5 mg/l of aluminum. Overall one of the most striking results was the difference between the numbers surviving in solutions containing 0.5 mg/l of calcium and less when compared with those in 1.0 mg/l of calcium or more. It would appear that although the relationship between calcium and aluminum in determining the fishery status of low pH lakes is complex, both ions will need to be considered in any attempt to explain the field observatons. SURVIVAL AND CONDITION OF RAINBOW TROUT (SALMO GAIRDNERI) AFTER EXPOSURES TO METHYL PARATHION, TRIPHENYL PHOSPHATE, AND DEF,
Fish and Wildlife Service, Columbia, MO.
D. Palawski, D. R. Buckler, and F. L. Mayer.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 5, p 614-620, May, 1983. 3 Tab, 11 Ref.

*Organophosphates, *Fish, *Survival, Agricultural chemicals, Defoliants, Pesticides, Hydraulic fluids, Methyl parathion, DEF, Triphenyl phosphate, Toxicity.

Toxicity data was sought for DEF, an aliphatic organophosphate defoliant; methyl parathion, an aliphatic/aromatic organophosphate insecticide; and triphenyl phosphate, an aromatic organophosphtae combined with various phosphate esters in mixtures to form hydraulic fluids. The protocol used for this study was also evaluated for possible use in assessing the effects of chemical spills on aquatic resources. One hundred fish were exposed under static water conditions for 96 hr to each toxicant in 30-liter stainless steel tanks. After the 96 hr exposure, a maximum of 40 survivors per exposure were removed from the tanks, stocked in 45 liter stainless steel tanks and reacclimated to clean well water. The 96-hr LC50s were 0.36 mg/l for triphenyl phosphate; 0.31 mg/l for DEF; and 2.8 mg/l for methyl parathion. Results obtained after 96 hr of static exposure indicated that methyl parathion at concentrations of 2.1, 2.4, and 2.8 mh/l produced the most deleterious effects to rainbow trout, causing mortalities of 37%, 38%, and 61% respectively. All survivors in each concentration were immobile and had distended abdomens at the end of the static exposure. Ability of survivors to recover after exposure to methyl parathion was significantly impaired during the first day after transfer to clean water. After this critical period no further mortality was noted. Survival after exposure was 28% for fish exposed to 2.1 mg/l of methyl parathion, but only 2% for fish exposed to 2.8 mg/l. No significant increase was noted in mortality of rainbow trout during the observation period following exposure to triphenyl phosphate. A biological effect noted in about 12% of the survivors exposed to the highest concentration of triphenyl phosphate was possible vertebral damage in the caudal area, resulting in spinal curvatures. (Baker-IVI)

SHORT-TERM STANDING CROP AND DIVERSITY OF PERIPHYTIC DIATOMS IN A EUTROPHIC RESERVOIR,
K. D. Hoagland.
Journal of Phycology, Vol. 19, No. 1, p 30-38, March, 1983. 7 Fig, 6 Tab, 62 Ref. 14-34-0001-6028.

Descriptors: *Diatoms, *Standing crops, *Species diversity, Periphyton, Weather, Turbulence, Substrates, Attachment, Wave action, Colonization, Eutrophication, Reservoirs.

Adverse weather and resultant turbulence caused sloughing of attached diatom communities during the first two weeks of colonization on artificial substrates. In contrast to Pacific macroalgal systems, older communities (8-12 d) were the most affected by wave action. Ash-free dry weight of the periphyton and diatom cell density generally increased, except following periods of high turbulence when losses of up to 80% occurred. The maximum cell density (400,000 diatoms/sq cm) and ash-free dry weight (2.9 mg/sq cm) are among the highest reported for similar conditions. Percent transmittance through the growth layer correlated significantly with cell density and ash-free dry weight and is recommended as a rapid method for measuring the relative accumulation of periphyton. Diatom diversity generally increased throughout the study period and did not clearly reflect the effects of disturbance as did standing crop. Comparisons of diatom diversity and community composition indicated that the three overlapping growth series were not significantly different and samples collected on the same date were not more similar than those of identical age. Combined with previous evidence, the present study indicates that the first two weeks of substrate exposure in the summer represented a colonization phase followed by rapid microsuccession. DISTRIBUTION OF HEMICELLULOSE-DECOMPOSING BACTERIA AND ENVIRONMENTAL CONDITIONS IN SEAWATER IN HIRO BAY,
Shimonoseki Univ. of Fisheries (Japan). Lab. of Microbiology.
M. Murakami, and H. Fujisawa.
Bulletin of the Japanese Society of Scientific Fisheries, Vol. 49, No. 3, p 455-462, March, 1983. 3 Fig, 3 Tab, 21 Ref.

Descriptors: *Pulp wastes, *Microbial degradation, *Hemicellulose, Heterotrophic bacteria, Effluent, Water pollution effects, Kraft mills, Seawater, Chemical oxygen demand, Marine environment, Hiro Bay, Japan.

On the coast of Hiro Bay in Seto Inland Sea, there is a kraft pulp mill whose effluent flows into the bay. Many workers have reported about organic pollutants and their influence on fishery in this area. Although microbiological work is indispensable for clarifying the mechanism of the decomposition of organic pollutants, little has been known about it. Therefore, a series of studies has been undertaken to clarify the microbial decomposition of hemicellulose in coastal waters polluted with pulp mill effluent. The distribution of heterotrophic bacteria and hemicellulose decomposing bacteria, and the environmental conditions of seawater in the above-mentioned area were investigated five times from 1979 to 1981. The results obtained can be summarized as follows: the population densities of heterotrophic bacteria, glucomannan-decomposing bacteria, xylan-decomposing bacteria and agar-decomposing bacteria per ml of seawater, were 100 to 10,000,000, 10 to 100,000, 10 to 10,000,000 and 10 to 100,000 respectively. The significance test of common coefficient regression analysis in the 1 m layer of seawater showed that the population density of bacteria and the value of COD decreased with the distance from pulp mill. The ratio of the population density of xylan-decomposing bacteria to the population density of heterotrophic bacteria in the 1 m layer of seawater was 10 to 1,000 times as high as that in the control area (Yoshimi Bay), and similar to that in other pulp mill polluted areas (Iwakuni waters). Therefore, it can be said that this ratio may be one of the suitable indices for the pollution from pulp mills. (Author's abstract)

A MODEL FOR THE DENSITY OF AEROMONAS HYDROPHILA IN ALBEMARLE SOUND, NORTH CAROLINA,
Puerto Rico Univ., Rio Piedras. Dept. of Biology.
T. C. Hazen.
Microbial Ecology, Vol. 9, No. 2, p 137-153, July, 1983. 8 Fig, 6 Tab, 35 Ref. RR-8102, 04F15844030, DE-AS09-76EY-0900.

Descriptors: *Aeromonas, *Mathematical models, *Water quality, Heterotrophic bacteria, Coliforms,Dissolved oxygen, Water temperature, Orthophosphate, Chlorophyll a, Kjeldahl nitrogen, Ammonia, Regression analysis, Epizootiology, Eutrophication, Reservoirs, Estuaries.

The abundance of Aeromonas hydrophila was measured monthly at 29 sites in Albemarle Sound, North Carolina and its tributaries from April 1977 through July 1979. Simultaneous measurements included heterotrophic plate count bacteria, fecal coliform bacteria, and 18 physical and chemical parameters. Using only 6 water quality parameters, multiple correlation and regression analysis of the data produced a best-fit regression which explained 38% of the variation observed in A. hydrophila density. The 6 water quality parameters included dissolved oxygen, temperature, orthophosphate, chlorophyll A trichromatic, total Kjeldahl nitrogen, and ammonia. Heterotrophic plate count bacteria and fecal coliform densities were highly correlated with A. hydrophila density, but made the model very unstable. The model was successfully tested against similar data collected for 2 other North Carolina reservoirs, Lake Norman and Badin Lake. Data from 10 sites in Badin Lake over 18 months and from 7 sites on Lake Norman over 5 months were not significantly different from the Albemarle Sound model. Conditions of water quality that may give rise to 'blooms' of A. hydrophila will simultaneously contribute to the probability of increased epizootics in fish in the southeastern United States. (Author's abstract)

CHANGES IN WATER AND SEDIMENT BACTERIAL COMMUNITY STRUCTURE IN A LAKE RECEIVING ACID MINE DRAINAGE,
Virginia Univ., Charlottesville. Dept. of Environmental Sciences.
R. A. Wassel, and A. L. Mills.
Microbial Ecology, Vol. 9, No. 2, p 155-169, July, 1983. 2 Fig, 5 Tab, 39 Ref. DEB-7906298.

Descriptors: *Acid mine drainage, *Bacteria, *Water pollution effects, Biological communities, Heterotrophic bacteria, Heavy metals, Sediment bacteria, Species diversity.

Water and sediment bacterial communities in a freshwater impoundment were studied over a 13-month period for stress-related responses to a point source of acid mine drainage (AMD). Comparisons of community structure were made on collections taken at the mouth of the acid stream, at a point 2 km downstream, and at the mouth of an uncontaminated stream. Monthly measurements of pH and specific conductance indicated the expected decrease in the AMD pollution with increasing distance from the source. Acridine orange direct counts did not differ significantly among the sites; however significantly fewer viable heterotrophs were observed by plate counts at the acid impacted station relative to the uncontaminated site. The diversity of the communities was significantly lower at the sites receiving mine drainage as compared with the unaffected station, and comparisons of community similarity showed that collections from the impacted sites were more like each other than like the control site. The assemblage at the latter site contained many bacterial guilds not found at the contaminated sites. The guilds unique to the control site showed a reduced in vitro ability to tolerate heavy metals as compared with the general community. (Author's abstract)

INVESTIGATIONS ON THE INFLUENCE OF COASTAL UPWELLING AND POLLUTED RIVERS ON THE MICROFLORA OF THE NORTHEASTERN ATLANTIC OFF PORTUGAL; I. SIZE AND COMPOSITION OF THE BACTERIAL POPULATION,
Kiel Univ. (Germany, F.R.). Inst. fuer Meereskunde.
G. Rheinheimer, and R. Schmaljohann.
Botanica Marina, Vol. 26, No. 3, p 137-152, March, 1983. 17 Fig, 3 Tab, 25 Ref.

Descriptors: *Eutrophication, *Bacteria, Upwelling, Marine environment, River flow, River mouth, Saprophytic bacteria.

Investigations conducted in May of 1981 off the western and southern coasts of Portugal indicate that upwelling dominated at this time throughout the area. Bacterial counts and biomass measurements were distinctly higher than in April of 1980. Bacteriological variables revealed differences between the northern and southern sections in accordance with the particular upwelling situations. Terrigenous influence proved to be restricted to the mouths of the rivers Douro and Tejo, and were evidenced through a rise in the numbers of saprophytes at the stations nearest the coast. Total bacterial counts exhibited only small differences compared to stations further offshore. The terrigenous influence was stronger in the the area of the mouth of the Tejo, where at a depth of 100 m, 1085 saprophytes/ml were counted. In general, total bacterial counts decreased with increasing depth, although in some cases an increase of bacterial numbers at depths of 500-1000 m was found. In certain locations the percentage of dividing cells in subsurface water layers was greater than at the surface. The distribution of a few morphologically distinguished groups of bacteria showed differences within the area of study and from other regions of the sea. (Moore-IVI)

SEWAGE POLLUTION AND THE INFAUNAL BENTHOS OF VICTORIA HARBOUR, HONG KONG,
Fisheries Research Station, Aberdeen (Hong Kong).
G. B. Thompson, and P. K. Shin.
Journal of Experimental Marine Biology and Ecology, Vol. 67, No. 3, p 279-299, March, 1983. 9 Fig, 5 Tab, 56 Ref.

Descriptors: *Water pollution effects, *Benthic fauna, *Wastewater pollution, Tidal currents, Harbors, Typhoon shelters, Abiotic areas, Polychaetes, Oligochaetes, Mollusks, Species diversity, Biomass, Biological communities, Hong Kong.

Victoria Harbor, Hong Kong, receives 800 mi
l/day of untreated sewage from 3.6 million pe
but is flushed by tidal currents at velocities u
1.1 m/s. Two replicate Smith-McIntyre grab
ples were collected at 66 stations in August
yielding a total of 5797 animals belonging t
species. Agglomerative hierarchical classifica
was used to delineate five station groups; a
group contained four stations where no fauna
found. All but one of the groups inhabited
sediments (>70% silt-clay) and could be pla
along a gradient conforming to the typical pat
of organic pollution effects found in boreal
temperate waters. Abiotic areas, found in encl
typhoon shelters, were successively replaced b
very poor fauna, a peak of opportunists, an ecot
point and a transition to normal fauna. The peal
opportunists was dominated by the oligochа
Thalassodrilides gurwitschi (Hrabe); the p
chaetes Capitella capitata (Fabricius) and Minu
cirrifera (Wiren) were also numerous. Ove
abundance was low (784 individuals/sq m) c
pared with opportunists in boreal and temper
waters. The remaining station group was found
coarser sediments (<40% silt-clay) and an infl
tion was observed in the log-normal distributio
individuals per species. Dominant species inclu
the bivalve Tapes philippinarum (Adams
Reeve) and the polychaete M. cirrifera; ove
abundance was high (1103 individuals/sq m).
general, pollution was assessed by the pattern
changes in number of species, abundance, biom
diversity and evenness, by log-normal distributi
of individuals per species, and by the indica
species M. cirrifera. When compared with earl
(1976) data, community conditions were genera
similar but the abundance of individual spec
varied greatly and M. cirrifera was absent. T
severely polluted area was about 15 sq km; this
similar in extent to offshore discharge sites a
indicates the importance of tidal flushing in t
inshore channel. (Author's abstract)

ors: *Hydrocarbons, *Oil pollution, *La- oastal areas, Sediments, Oysters, Bioaccumulation, Oil spills, Storms, Oil industry, Tabasco, Mexico.

More than 100 samples of sediments and oysters (Crassostrea virginica) were collected at 27 stations located in the Carmen-Machona and Mecoacan lagoons in Tabasco, Mexico, during four periods: October, 1979; January, March, and May, 1980. The majority of values obtained for total hydrocarbon concentrations in sediments are below 70 ppm; they correspond to hydrocarbon concentrations in coastal areas considered to be non-polluted. The highest concentrations (1060 and 305 ppm) reflect the influence of oil spilled in the Ixtoc-I accident, which was carried to the coast by tropical storm 'Henry' in September, 1979. The remaining values between 80 and 150 ppm (18%) are probably due to fluvial discharges and runoff from adjacent areas where exploration, exploitation and crude oil refinement are carried out. The results obtained in May are all less than 70 ppm, which could indicate that fossil hydrocarbons do not remain in the sediments of the lagoon studied because of the great dynamism of the coastal ecosystems. The results obtained for oysters coincide with those reported for bivalves from lagoons, bays and canals affected by oil industry activities and accidents. The greatest concentrations of hydrocarbons in oysters were observed principally in October, which may indicate that these organisms had bioaccumulated compounds or adsorbed particles of oil from the Ixtoc-I accident. In general, the values obtained for oysters indicate chronic pollution. (Moore-IVI)

ACUTE TOXICITY OF CHLORINE AND BROMINE TO FATHEAD MINNOWS AND BLUEGILLS,
Du Pont de Nemours (E.I.) and Co., Aiken, SC. Savannah River Lab.
E. W. Wilde, R. J. Soracco, L. A. Mayack, R. L. Shealy, and T. L. Broadwell.
Bulletin of Environmental Contamination and Toxicology, Vol. 31, No. 3, p 309-314, September, 1983. 2 Tab, 19 Ref. DE-AC09-76SR00001.

Descriptors: *Chlorination, *Biocides, *Toxicity, *Bromine, Fish, Cooling water, Antifouling agents, Residual chlorine, Residual bromine, Fathead minnows, Bluegills.

Several alternatives to chlorination have recently been proposed including the use of a bromine-based biocide, 1-bromo-3-chloro-5,5-dimethylhydantoin (BCDMH). The relative toxicity of chlorine and BCDMH to three types of fish were compared in a freshwater system used for cooling a nuclear reactor. Flow-through 96-hr toxicity tests were conducted using water from Par Pond, a reactor cooling reservoir at the Savannah River Plant near Aiken, S.C. Juvenile and yearling fathead minnows and young-of-the-year bluegills were used as test organisms. Median lethal concentrations for total residual chlorine (TRC) and total residual bromine (TRB) were statistically compared. Juvenile fathead minnows were significantly more tolerant of TRB than TRC. TRC and TRB 96-hr median lethal concentrations for adult fathead minnows were not significantly different. Bluegills were significantly more tolerant of TRC than TRB. Bluegills were significantly more tolerant of both biocides than were fathead minnows. Adult minnows were significantly more tolerant of both biocides than juvenile minnows. (Moore-IVI)

COMPARATIVE STUDY OF THE EFFECTS OF METALS ON THE SETTLEMENT OF CRASSOSTREA GIGAS,
Port Elizabeth Univ. (South Africa). Dept. of Zoology.
H. R. Watling.
Bulletin of Environmental Contamination and Toxicology, Vol. 31, No. 3, p 344-351, September, 1983. 2 Fig, 3 Tab, 9 Ref.

Descriptors: *Oysters, *Heavy metals, *Water pollution effects, *Larvae, Growth stages, Zinc, Cadmium, Copper, Lead, Manganese, Nickel, Cobalt, Chromium, Spat, Behavior, Mortality.

The effects of eight elements on Crassostrea gigas larval settlement and spat growth have been investigated using a single larval culture for each comparative test. The metal concentrations were chosen in the range to cause sub-lethal rather than lethal effects. Zinc, cadmium, copper, lead, manganese, nickel, cobalt, and chromium were tested at 10 and 20 micro g/l. Experimental observations included growth and behavior in addition to mortality. Of the eight elements studied, only copper and manganese were not detrimental to C. gigas settlement success. Larval behavior was not noticeable different for the various treatments in this experiment. Zinc and lead delayed settlement, and copper and cobalt induced early settlement. Zinc, cadmium, copper, lead, manganese, nickel, cobalt and chromium in the 10-20 micro g/l range all caused a reduction in spat growth during metal exposure. Low copper concentrations (20-40 micro g/l), added to the water immediately prior to larval settlement and for only two or three days may stimulate larval settlement. (Moore-IVI)

COMPARATIVE BIOACCUMULATION AND ELIMINATION OF HCH ISOMERS IN SHORT-NECKED CLAM (VENERUPIS JAPONICA) AND GUPPY (POECILIA RETICULATA),
Moji Public Health Center (Japan).
Y. Yamato, M. Kiyonaga, and T. Watanabe.
Bulletin of Environmental Contamination and Toxicology, Vol. 31, No. 3, p 352-359, September, 1983. 4 Fig, 1 Tab, 11 Ref.

Descriptors: *Bioaccumulation, *Pesticide residues, *Elimination, Insecticides, Guppy, Clam, HCH, Lindane, Chlorinated hydrocarbons.

In Japan, HCH had been one of the most applied insecticides to arable fields, especially to rice paddies. Residues of alpha, beta, and delta HCH have been detected as well as insecticidally active gamma HCH in the environment because technical grade HCH had been formulated and marketed as HCH insecticide. Comparative bioaccumulation and elimination of 4 HCH isomers by short-necked clam (Venerupis japonica) and guppy (Poecilia reticulata) were examined. Alpha, beta, gamma, and delta HCH were dissolved in water at concentrations of 1, 2, 1, and 2 ppb, respectively and the clams or guppies were exposed for 10 days, and then removed to HCH-free flowing water. The guppy rapidly bioaccumulated HCH isomers and the concentrations reached a plateau on the 4th day. The bioaccumulation ratios (BR) of alpha, beta, gamma, and delta HCH were 706, 1043, 697, and 648 times on that day, respectively. Concentrations of HCH isomers in the guppy smoothly decreased on the first day after replacement to HCH-free water, and constantly declined afterwards. Short-necked clams rapidly absorbed HCH isomers, and the concentrations reached a plateau on day three. The BR of alpha, beta, gamma, and delta HCH were 161, 127, 121, and 272 times, respectively. Concentrations of each HCH isomer in clams constantly decreased after replacement to HCH-free water. (Moore-IVI)

CHRONIC TOXICITY TO FATHEAD MINNOW PIMEPHALES PROMELAS OF WASTEWATER FROM A CONVENTIONAL WASTEWATER TREATMENT SYSTEM RECEIVING ORGANIC PRIORITY POLLUTANTS,
Environmental Research Lab.-Duluth, Cincinnati, OH. Newtown Fish Toxicology Station.
Q. H. Pickering.
Environmental Pollution (Series A), Vol. 31, No. 3, p 105-117, June, 1983. 4 Tab, 17 Ref.

Descriptors: *Effluent, *Toxicity, Fathead minnows, Chlorination, Hatching, Growth, Larval growth stages, Wastewater treatment, Organic compounds, Priority pollutants, Mortality.

Chronic toxicity tests were made with unchlorinated and dechlorinated effluent from a conventional wastewater treatment system receiving 22 organic

priority pollutants. The early-life-stage (ELS) tests began with fathead minnow embryos less than 1-day old and exposure continued for 30 days post hatch. There was no significant difference in hatchability between any effluent concentration (5.0-0.16%) and control. Survival and growth of larvae-juveniles in all unchlorinated concentrations were similar to controls. The chronic value for this exposure was > 5% and the acute-chronic ratio was < 6.6. Survival and growth of fish in 5% dechlorinated effluent were significantly less than survival and growth of control fish. Survival of fish in the 2.5% effluent was similar to survival of control fish. However, growth of these fish was only 75% of control fish and was significantly less than growth of control fish. Survival and growth of fish in the 1.3% effluent were not different from controls. The chronic value of the dechlorinated effluent was 1.8% and the acute-chronic ratio, about 19.

A NOTE ON THE EFFECTS OF CRUDE OIL ON MICROBIAL ACTIVITIES IN A STREAM SEDIMENT,
Oregon State Univ., Corvallis. Dept. of Microbiology.
J. H. Baker, and R. Y. Morita.
Environmental Pollution (Series A), Vol. 31, No. 2, p 149-157, June, 1983. 1 Fig, 1 Tab, 15 Ref. NOAA Contract 03-05-022-68.

Descriptors: *Oil pollution, *Stream sediments, *Microorganisms, Metabolism, Nitrogen fixation, Carbon dioxide, Methanogenesis, Phosphatase, Mud, Hydrocarbons.

Rivers are the most important transport systems for hydrocarbon wastes which may arise from both accidental spills and controlled effluents. However, the influence of crude oil on normal metabolic processes occurring in river sediments has been largely neglected. The work described was a pilot study designed to demonstrate the effects of spilled oil on a wide range of microbial activities in a stream mud. The stream chosen was Berry Creek, a controlled minor tributary of the Willamette watershed in western Oregon. Rates of CO2 production, nitrogen fixation and methanogenesis, Vmax for glucose, and phosphatase levels were all determined in the presence and absence of crude oil. Four weeks after the oil addition the Vmax and phosphatase levels were significantly reduced and remained so, but methane and CO2 production rates were both significantly increased. Nitrogen fixation was not affected by 0.1% (v/v) oil, but was reduced after 8 weeks by 1.0% oil.

ACUTE TOXICITY OF A DITHIOCARBAMATE FUNGICIDE, THIRAM, WITH REGARD TO SEVERAL SPECIES OF FRESHWATER ANIMALS (TOXICITE AIGUE D'UN FONGICIDE DITHIOCARBAMATE, LE THIRAME, VIS A VIS DE PLUSIEURS ESPECES ANIMALES D'EAU DOUCE),
Paris-11 Univ., Orsay (France). Lab. de Zoologie.
J. Seuge, D. Marchal-Segault, and R. Bluzat.
Environmental Pollution (Series A), Vol. 31, No. 3, p 177-189, July, 1983. 2 Fig, 2 Tab, 16 Ref.

Descriptors: *Toxicity, *Thiram, Fungicides, Mollusks, Amphibians, Crustacea, Insects, Platyhelminths.

Acute toxicity experiments (24, 48, 72 and 96 h) were carried out with an aqueous suspension of thiram (commercial powder titered at 80%). The animal sensitivity was very variable, the 24-h and 96-h LC 50's being 0.53 ppm and 0.048 ppm (Dugesia gonocephala, plathelminth), 1882 ppm and 61 ppm (Asellus aquaticus, crustacean), 0.017 ppm and 0.013 ppm (Xenopus laevis, amphibian, stage 47), 0.025 ppm and 0.021 ppm (Xenopus, stage 53). In all cases, the LC50 related to time can be described by the law $y = axb$, this permitted us to compare the present results with those already obtained in Lymnaea stagnalis (molluscan), Gammarus pulex (crustacean) and larvae of Cloeon dipterum (insect). The slopes of these curves indicate three types of reaction: one in the two crustaceans (Asellus and Gammarus), one in Lymnaea and Dugesia and one in Cloeon and Xenopus larvae. The six species studied can be classified according to increasing sensitivity as follows: Asellus, Lymnaea, Gammarus and Cloeon larvae at the same level, Dugesia and Xenopus larvae; the spectrum of thiram activity is in the range 10 pptm to 5000-6000ppm: it is then very large. It can be concluded that thiram, a fungicide intensively used in agriculture, presents a real threat to all freshwater fauna. (Author's abstract)

TOXICITY, ACCUMULTION AND CLEARANCE OF AROMATIC HYDROCARBONS IN DAPHNIA PULEX,
Ottawa Univ. (Ontario). Dept. of Biology.
R. G. Trucco, F. R. Engelhardt, and B. Stacey.
Environmental Pollution (Series A), Vol. 31, No. 3, p 191-202, July, 1983. 1 Fig, 3 Tab, 17 Ref.

Descriptors: *Hydrocarbons, *Toxicity, *Bioaccumulation, Daphnia, Metabolism, Benzene, Naphthalene, Phenanthrene, Benzo(a)anthracene, Benzo(a)pyrene.

Exposure of the zooplankter Daphnia pulex to five aromatic hydrocarbons in water determined an increasing toxicity in the order of benzene, naphthalene, phenanthrene, benzo(a)anthracene to benzo(a)pyrene, as measured by 96-h LC50 values. These ranged exponentially from 15 mg/l for benzene to 5 micro g/l for benzo(a)pyrene. Accumulation after 24 h of exposure was found to be specific to the aromatic hydrocarbon, measured as 14C-aromatic hydrocarbon load, as well as to the vector of exposure. Naphthalene accumulation was greatest, about 11 thousand times from algal food, while benzo(a)anthracene and benzo(a)pyrene accumulated more from the water, about one and three thousand times, respectively. Benzene was least accumulated. Clearance of the accumulated aromatic hydrocarbons occurred rapidly in all cases but naphthalene. Naphthalene clearance by 72 h after cessation of exposure was only 17 to 30% of the 24-h hoad, while the other four hydrocarbons were cleared by an average of 85%. (Author's abstract)

ALKYL LEAD POLLUTION AND BIRD MORTALITIES ON THE MERSEY ESTUARY, UK, 1979-1981,
Institute of Terrestrial Ecology, Huntingdon (England). Monks Wood Experimental Station.
K. R. Bull, W. J. Every, P. Freestone, J. R. Hall, and D. Osborn.
Environmental Pollution (Series A), Vol. 31, No. 3, p 239-259, August, 1983. 2 Fig, 5 Tab, 17 Ref.

Descriptors: *Birds, *Mortality, *Trialkyl lead, Organolead compounds, Waterfowl, Toxicity, Invertebrates, Industrial wastes, Chemical industry, Estuaries, Mersey Estuary, England.

In autumn 1979 about 2400 birds of many species were found dead and sick on the Mersey Estuary, UK, which is an important wader and wildfowl wintering area. Smaller mortalities occurred in 1980 and 1981. Affected birds contained elevated lead levels, much of the lead being in the form of alkyl lead. Apparently healthy birds contained lower amounts of alkyl lead but still enough to cause some ill-effects. Trialkyl lead compounds (on the order of 80 kg/day) were discharged into the Mersey-Manchester Ship Canal system from petrochemical works at levels which would account for the levels found in invertebrates on which the birds could feed. Such concentrations in invertebrates could easily lead to birds accumulating the levels of trialkyl lead found in their tissues. Several thousand apparently healthy birds were apparently also at risk. (Moore-IVI)

MALATHION INDUCED HEMATOLOGICAL AND BIOCHEMICAL CHANGES IN THE INDIAN CATFISH HETEROPNEUSTES FOSSILIS,
Gorakhpur Univ. (India). Dept. of Zoology.
J. Mishra, and A. K. Srivastava.
Environmental Research, Vol. 30, No. 2, p 398, April, 1983. 3 Tab, 33 Ref

Descriptors: *Toxicity, *Malathion, *Catfish, ticides, Metabolism, Chloride, Blood, Patho

The acute toxicity and effects of duration of thal exposure to malathion were determined Indian catfish (Heteropneusters fossilis). Fis posed to the pesticide for 2, 6, 12, 48, and showed muscle glycogenolysis with concom hyperglycemia at all intervals; hepatic glyc was unaffected. Malathion was also associated hypochloremia at 2 and 6 hr and hyperchlor at 48 and 96 hr; blood chloride concentration unaffected at 12 hr. Fish developed erythro and leukopenia; lowered hematocrit and hem bin content and hypercoagulability of blood also observed. The data showed that homeos and hemostatic mechanisms are disturbed malathion treatment and could be helpful for uating pesticide toxicosis in fish. (Author's stract)

Descriptors: *Industrial wastewater, *Plant pat ogy, Effluent, Rice, Seedlings, Nucleic a Chlorophyll, Pigments, Food-processing waste

The effect of an effluent from a distillery of a s factory on cellular macromolecular composi and indophenol photochemical activity of isol chloroplasts of rice (Orvza sativa c.v. Musho seedlings was investigated. The effluent, whic known as spend wash, contains high concen tions of various cations and anions. The total ments, proteins, and nucleic acids of rice seedl declined with an increase in effluent concentra and the time of incubation. The loss in content macromolecules like deoxyribonucleic (DNA), ribonucleic acid (RNA), and protein relatively more marked in the root than in shoot. RNA and chlorophyll (Chl) contents of seedlings were found most susceptible to effl stress. Loss in Hill reaction activity measure photoreduction of 2,6-dichlorophenol indoph (DCPIP) of isolated chloroplasts could be corre ed in a general way with the loss of pigme proteins and nucleic acids. Diphenyl carbaz induced and Mn(2+)-induced restoration of los DCPIP photoreduction suggests that the dam of oxygen evolving systems is the initial site action of the effluent. (Moore-IVI)

al Engineering, Vol. 64, No. 5, p 7-9,
2 Fig.

s: *Acid rain, *Reviews, United States,
anada, Water pollution sources, Acidity,
g, Environmental effects.

em confronting the researcher examining
m of acid rain is the lack of essential records much before the mid-sixties. Descriptions of 19th and early 20th century industrial operations both in the United States and Europe suggest a higher level of polluted air and water than would be tolerated now. A pH of 5.6 is considered normal. Rain and snow in particularly vulnerable areas may consistently measure less than 4.5 pH. The disposition of atmospheric contaminants occurs from two related atmospheric processes often identified as rainout and washout. A plan has been proposed where Canada and the US will have a permanent acid deposition measurement system with specific monitors strategically placed. With the usual systems for monitoring rain, only cations and anions can be measured, but not trace elements. The application of limestone to acidified lakes and streams requires considerable knowledge both of input sources to the lake and of water turnover times. Liming tends to increase aluminum and cadmium accumulations in waters with 4-6 pH levels, thus intensifying the likelihood of fish kills. While electric utilities often are cited as the major contributor to the problem, seldom does one hear of that industries contributions toward research funding to solve the problem. Without accurate long-term monitoring data, researcher have had to calculate acidity trends in presumably vulnerable areas. At times they may have had to assume that forest, crop and fish kills came from acid rain as they had no way to assess other factors such as whether some soils and waters in specific areas have ever consistently supported certain crops and certain types of aquatic life. STUDIES OF A SPRING PHYTOPLANKTON BLOOM IN AN ENCLOSED EXPERIMENTAL ECOSYSTEM. I. BIOCHEMICAL CHANGES IN RELATION TO THE NUTRIENT CHEMISTRY OF WATER,
Institute of Oceanographic Sciences, Wormley (England).
R. J. Morris, M. J. McCartney, and G. A. Robinson.
Journal of Experimental Marine Biology and Ecology, Vol. 70, No. 3, p 249-262, August, 1983. 7 Fig, 2 Tab, 57 Ref.

Descriptors: *Diatoms, *Eutrophication, *Nutrients, Lochs, Biochemistry, Species composition, Decomposition, Metabolism, Coastal waters, Loch Ewe, Scotland.

A spring bloom of diatoms which occurred in large enclosed ecosystem bags at Loch Ewe, Scotland, during 1980, has been the subject of a chemical study. Changes observed in the general biochemical composition of the diatoms during the bloom are compared with the species distribution and changes in the nutrient chemistry of the bag water. The results indicate that major changes in cell biochemistry are associated with the growth, development, and decay of a diatom bloom, particularly if one or more nutrients become limiting. Of particular note is the growth of carbohydrate levels in the cells when lipid and protein levels fall and the apparent shift in lipid metabolism from mainly non-polar lipids at the onset of growth to more polar lipids as the bloom proceeds, then back to less polar lipids as phosphate becomes limiting. MICROBIOLOGICAL SURVEY OF ADIRONDACK LAKES WITH VARIOUS PH VALUES,
Rensselaer Polytechnic Inst., Troy, NY. Dept. of Biology.
C. W. Boylen, M. O. Shick, D. A. Roberts, and R. Singer.
Applied and Environmental Microbiology, Vol. 45 No. 5, p 1538-1544, May, 1983. 5 Fig, 3 Tab, 35 Ref.

Descriptors: *Microorganisms, *Hydrogen ion concentration, *Oligotrophic lakes, *Bacteria, Adaptation, Heterotrophic bacteria, Acid rain, Adirondack lakes, New York.

Atmospheric acidic deposition has not been well described in terms of its effects on aquatic microbial populations. Many of the lakes in the Adirondack region of New York State are particularly sensitive to high H(+) inputs from acidic deposition. It is important that these ecosystems be examined so that future changes can be appraised. Nine high-altitude oligotrophic Adirondack lakes having water of pH 4.3 to 7.0 were surveyed for total bacterial numbers and possible adaptation of the microbial communities to enviromental pH. The number of heterotrophic bacteria from water samples recoverable on standard plate count agar were low (10 to 1000 per ml) for most of the lakes. Acridine orange direct counts were approximately two orders of magnitude higher than plate counts for each lake. Sediment aerobic heterotrophs recovered on standard plate count agar ranged from 14000 to 1,300,000 per g of sediment. Direct epifluorescence counts of bacteria in sediment samples ranged from 3,000,000 to 1.4 x 10 to the 7th power per g. Low density values were consistent with the oligotrophic nature of all the lakes surveyed. There were no apparent differences in numbers of bacteria originally isolated at pH 5.0 and pH 7.0 between circumneutral lakes (pH $>$ 6.0) and acidic lakes (pH $<$ 5.0). Approximately 1,200 isolates were recultured over a range of pH from 3.0 to 7.0. Regardless of the original isolation pH (pH 5.0 or pH 7.0), less than 10% of the isolates grew at pH $<$ 5.0. Those originally isolated at pH 5.0 also grew at pH 6.0 and 7.0. Those originally isolated at pH 7.0 preferred pH 7.0, with 98% able to grow at pH 6.0 and 44% able to grow at pH 5.0. A chi-square contingency test clearly showed ($P < 0.005$) that two distinct heterotrophic populations had been originally isolated at pH 5.0 and pH 7.0, although there is undoubtedly some overlap between the two populations. (Moore-IVI)

EFFECTS OF METALS ON METHANOGENESIS, SULFATE REDUCTION, CARBON DIOXIDE EVOLUTION, AND MICROBIAL BIOMASS IN ANOXIC SALT MARSH SEDIMENTS,
State Univ. of New York at Stony Brook. Marine Sciences Research Center.
D. G. Capone, D. D. Reese, and R. P. Kiene.
Applied and Environmental Microbiology, Vol. 45, No. 5, p 1586-1591, May, 1983. 1 Fig, 2 Tab, 25 Ref. NOAA grant NA-80-RAD-00057, EPA grant R-809475-01-0, NSF grant OCE-82-00157.

Descriptors: *Salt marshes, *Sediments, *Microorganisms, *Heavy metals, *Anaerobic conditions, *Metabolism, Methane production, Carbon dioxide, Sulfates, Water pollution effects.

The effects of several metals on microbial methane, carbon dioxide, and sulfide production and microbial ATP were examined in sediments from Spartina alterniflora communities. Anaerobically homogenized sediments were amended with 1,000 ppm (ratio of weight of metal to dry weight of sediment) of various metals. Time courses in controls were similar for CH4, H2S, and CO2, with short initial lags (0 to 4 h) followed by periods of constant gas production (1 to 2 days) and declining rates thereafter. Comparisons were made between control and experimental assays with respect to initials rates of production (after lag) and overall production. Methane evolution was inhibited both initially and overall by CH3HgCl, HgS, and NaAsO2. A period of initial inhibition was followed by a period of overall stimulation with Hg, Pb, Ni, Cd, and Cu, all as chlorides, and with ZnSO4, K2CrO4, and K2Cr2O7. Production of CO2 was generally less affected by the addition of metals. Inhibition was noted with NaAsO2, CH3HgCl, and Na2MoO4. Minor stimulation of CO2 production occurred over the long term with chlorides of Hg, Pb, and Fe. Sulfate reduction was inhibited in the short term by all metals tested and over the long term by all but FeCl2 and NiCl2. Microbial biomass was decreased by FeCl2, K2Cr2O7, ZnSO4, CdCl2, and CuCl2 but remained generally unaffected by PbCl2, HgCl2, and NiCl2. Although the majority of metals produced an immediate inhibition of methanogenesis, for several metals this was only a transient phenomenon followed by an overall stimulation. The initial suppression of methanogenesis may be relieved by precipitation, complexation, or transformation of

the metal (possibly by methylation), with the subsequent stimulation resulting from a sustained inhibition of competing organisms (e.g., sulfate-reducing bacteria). For several environmentally significant metals, severe metal pollution may substantially alter the flow of carbon in sediments. (Author's abstract)

REPORT ON EUTROPHICATION STUDIES IN THE U.S.S.R.,
Moscow State Univ. (USSR). Dept. of General Ecology and Hydrobiology.
A. M. Ghilarov.
Water Resources, Vol. 17, No. 6, p 607-611, June, 1983. 39 Ref.

Descriptors: *Eutrophication, *USSR, *Nutrients, Pollution load, Municipal wastewater, Nonpoint pollution sources, Cyanophyta, Reservoirs, Mathematical models, Prediction, Phytoplankton, Biomass recovery.

Some results of eutrophication studies in the USSR are briefly reviewed. There are many lakes and man-made reservoirs in the USSR that show symptoms of eutrophication caused mainly by increasing nutrient loading from agricultural land and from municipal wastes. Especially strong eutrophication and heavy blooms of Cyanophyta occur in Dnieper-impounding reservoirs. Eutrophication has not yet touched such large Asian lakes as Issyk-Kul and Baikal, the water quality of which is controlled by special governmental decisions. The enormous number of different freshwater bodies located in various natural zones and in the regions with different human influence makes the forecasting of eutrophication important. Mathematical modeling of eutrophication is being developed in the USSR, along with other methods for the prediction of eutrophication. Although eutrophication most frequently results in a vast development of phytoplankton, in some waters where macrophytes are abundant, eutrophication may not result in blooms for a long time. Prevention of eutrophication can be accomplished by reduction of nutrient input in industrial and municipal wastes. Preliminary work has been done on the recovery of biomass from eutrophic waters and its utilization for fertilizer or as a raw material. (Moore-IVI)

ACID PRECIPITATION: WHAT IS IT DOING TO OUR FORESTS,
Environmental Law Inst., Washington, DC.
G. S. Wetstone, and S. A. Foster.
Environment, Vol. 25, No. 4, p 10-12 and 38-40, May, 1983. 2 Fig, 35 Ref.

Descriptors: *Acid rain, *Forests, Rainfall, Air pollution, Sulfur dioxide, Sulfates, Acidity, Soil properties, Soil chemistry.

Evidence is growing of serious problems in forests of the Central European region and eastern North America. In West Germany, fully 560,000 hectares of forests have recently been damaged. Trees have died in 60,000 ha of the nation's forests, and those in another 100,000 ha are reported to be seriously damaged. In Eastern Europe sulfur dioxide emission levels are extremely high. More than 500,000 ha of forests in Czechoslovakia have been severely damaged. Only recently has acid deposition emerged as a potentially sweeping threat to forests, especially in Central Europe. Some of the devastation is brought about as a consequence of contact between acid waters and the plant tissues. Rainfall in the pH range of 3.0 to 4.0 has been shown to cause tissue injury which can ultimately reduce forest growth. However, rainfall at such a low pH level is not common. Preliminary evidence suggests that indirect effects resulting from acid-induced soil changes are far more important. Acid deposition upsets the natural balance in the soils. Negatively charged sulfate ions, after accumulating in soils, can be washed out by rains, carrying with them nutrients such as calcium and magnesium. Acid conditions also slow the bacterial decompositon needed for the continued production of nutrients. In the long term pollution induced nutrient depletion accelerates the natural forest aging process, leading to the eventual exhaustion of the soil's ability to sustain tree growth. Acid-induced forest impacts are probably magnified in some instances by the increases in rainwater acidity as it passes through the forest canopy and runs down the tree bark, adsorbing in the journey dry-deposited acids present on the surfaces of plants. It is not certain at present whether acid-afflicted forests can be saved or whether acid induced impacts on forests or forest soils reversed. (Baker-IVI)

5D. Waste Treatment Processes

NEW WASTEWATER PROCESS CUTS PLANT COSTS 60%,
Burns and McDonnell, Kansas City, MO.
S. Christopher, and R. Titus.
Civil Engineering, Vol. 53, No. 5, p 39-41, May, 1983. 3 Fig.

Descriptors: *Wastewater treatment, *Biological wastewater treatment, System design, Clarifiers, Sludge digestion, Costs, Municipal wastewater.

A new concept in biological treatment for municipal wastewater combines the aerator and the clarifier into one basin and can thereby slash capital costs up to 60% and operation and maintenance costs up to 45%. Raw sewage enters the treatment system at the aeration basin, is aerated, then passes beneath an innovative intrachannel clarifier. A portion of the mixture of wastewater and activated sludge, commonly called mixed liquor, rises into the clarifier through openings in the clarifier bottom panels. Solids are separated, fall down through the openings and return to the continuously flowing mixture below. Effluent is removed in the upper portion of the clarifier through orifice pipes submerged about one foot beneath the water's surface. As there are no sludge blankets, the full depth of the clarifier is available for maximum settling. Solids settling downward from the quiescent zone also act as a filter to remove materials in the liquor that are flowing up into the quiescent zone. Under varying operating conditions sustained overflow rates ranged from 600 to 2,100 gallons per day per square foot and the BODs and suspended solids effluent requirements were still met. Effluent quality is not significantly degraded when running at very high flow rates due in part to the capability of the clarifer to distribute flow evenly across the entire surface area and to the capability of the submerged orifice effluent system to dampen peak flows. Descriptors: *Lime, *Neutralization, *Acid mine drainage, *Industrial wastewaters, Precipitation, Computers, Simulation, Adsorption, Wastewater treatment, Iron, Magnesium, Manganese, Zinc, Metals.

Appropriate disposal of acid-bearing waters resulting from base-metal industrial works and coal mine drainage continues to be a major problem. Because of economic considerations, lime neutralization with subsequent precipitation is one of the most popular techniques for treatment of these wastewaters. Lime neutralization of acidic wastewaters can prove to be an effective treatment process provided sufficient lime is added. The chemical changes that occur in the system are extensive and varied. Precipitation is predominant with complexation, oxidation, and adsorption playing major roles. Total chemical analyses have identified the chemical changes, and controlled laboratory simulations have identified the relative importance of the physical-chemical processes. The transfer of O2 and CO2 from the atmosphere does not play a major role in the chemistry of t
ring the metals from solution to the solid

-year study in which enteroviruses were ed at a 56-ML/d (15-mgd) advanced ater treatment plant is summarized. The train included high pH-lime treatment, air g, recarbonation, prechlorination, multime- dia filtration, granular activated carbon adsorption, reverse osmosis demineralization, and final chlorination. The influent and effluent were sampled on the average of once per week. During this study, viruses were detected twice in chlorinated effluent at very low levels and were associated with operational problems of the final disinfection process. Subsequent dilution by blending and injection of the final effluent into a groundwater aquifer, which resulted in additional dilution and treatment, has produced a water that is essentially free of enteroviruses. ODOUR CONTROL IN SOLID WASTE MANAGEMENT,
Imperial Coll. of Science and Technology, London (England). Public Health Engineering Lab.
J. M. Baker, C. J. Peters, R. Perry, and C. P. V. Knight.
Effluent and Water Treatment Journal, Vol. 23, No. 4, p 133-138, April, 1983. 2 Fig, 2 Tab, 36 Ref.

Descriptors: *Odor control, *Solid wastes, Wastewater treatment, Sulfur, Nitrogen, Oxidation, Cost analysis, Anaerobic conditions, Hydrocarbons, Fatty acids.

The decision to implement odor abatement measures in the management of solid wastes disposal will generally arise as a result of odor nuisance complaints. Odor emissions arise from the disturbance of organic material undergoing anaerobic fermentation and are generally caused by the presence of sulfur and nitrogen containing compounds, fatty acids, esters and naturally occurring hydrocarbons. Odor control may be best carried out by efforts to keep the material aerobic, to avoid disturbance of anaerobic material and to provide coverings which prevent gaseous emission; by camouflaging the smell to make it acceptable; and by oxidation of the malodorants to the odorless end products of carbon dioxide and water. If a method of oxidation is chosen, then financial, energy and space requirements, in addition to volume and concentration of odor and efficiency of odor reduction required will dictate the method to be used. There is evidently a need for further study in the chemical nature of odorants associated with solid waste degradation. While sensory methods for assessing the level of oxidant odorants are now well stabilized, the results they give are necessarily subjective. Instrumental analytical techniques must be developed to chemically identify the major constituents of the odor and hence enable a suitable method of abatement or eradication to be used. (Baker-IVI)

RECLAMATION OF WASTEWATER CONSTITUENTS BY ION EXCHANGE, PART I. REVIEW OF FLOWSHEETS FOR THE PROCESSES - CONTINUED FROM VOLUME 23 NUMBERS 1 AND 2,
B. A. Bolto, and L. Pawlowski.
Effluent and Water Treatment Journal, Vol. 23, No. 4, p 159-167, April, 1983. 6 Fig, 3 Tab, 56 Ref.

Descriptors: *Reclaimed water, *Ion exchange, *Metal finishing wastes, Nickel, Copper, Mercury, Heavy metals, Zinc, Molybdenum, Selenium, Arsenic, Resins.

The typical ion exchange system for recycling the constituents of rinse water coming from chromic and cyanide operations of metal finishing plants consists of a cation exchanger unit followed by an anion exchange unit. The recovery of metals is possible when the streams of rinse water to be treated are separated, allowing the regeneration effluents to be appropriately mixed. Another method of treatment is to separate some of the heavy metals from the mixture. With conventional resins it is possible to obtain selective removal of heavy metals from effluents. Specific resins for the selective removal of ions are also known. The biggest environmental problem associated with nickel arises from metal finishing plants where its recovery is possible only if the nickel-bearing effluent is separated from other effluents. There are several copper baths which contain sulfate or chloride, and the general concept of their treatment is as for the treatment of nickel bearing effluents. Another application of ion exchange for the recovery of copper is the treatment of effluents from leaching operations in copper production. For removal of zinc, the zinc cation may be taken up by a cation exchanger or a chelate resin, and the anion by an anion exchanger. Most of the mercury resulting from industrial waste comes from chlorine and caustic manufacturing plants. Re-use of mercury from the wastewater treatment can reduce the cost of treatment by about 25%. Recovery of precious metals and rare elements is also possible. (Baker-IVI)

FLOCCULATION TEST METHODS,
University Coll., London (England). Dept. of Civil Engineering.
J. Gregory.
Effluent and Water Treatment Journal, Vol. 23, No. 5, p 199-205, May, 1983. 3 Fig, 35 Ref.

Descriptors: *Flocculation, *Testing procedures, Zeta potential, Colloids, Sedimentation, Permeability, Electrophoresis, Jar testing, Chemical coagulation, Water treatment, Wastewater treatment.

The essential steps in the flocculation of a water containing suspended particles are destabilization of the particles by eliminating any repulsion between them, and collisions of destabilized particles to form aggregates, or flocs. Proper operation of a flocculation process requires that the correct dosages of reagents be used, with efficient mixing, and that the destabilized particles are provided with sufficient contact opportunity to form aggregates of the required size and properties. The flocculation test procedure establishes the optimum chemical conditions for floc formation. Ideally the test procedure should simulate the operation of a full-scale unit and be capable of predicting plant performance on the basis of laboratory trials. Measurement of the particle charge as a function of reagent dose can give a good indication of the optimum dosage. The most common approach is to measure the zeta potential of the particles. Another technique which can give similar information without the use of elaborate equipment is colloid titration. This test depends on the fact that water-soluble polyelectrolytes of opposite charge to the suspension particles will adsorb strongly until the particle charge is neutralized. Properties of flocculated suspensions which should be determined include sedimentation and permeability. The jar test procedure can be used to determine many of the properties of the flocculated suspensions. However, such testing has disadvantages, including time consumed to complete the test procedure. Alternatives to the jar test are being developed with two different aims: to provide a test method which is more rapid and convenient giving information on optimum chemical conditions; and to give result which are more closely related to flocculation performance in actual flocculation plants. A COMPARISON OF AN INDUSTRIAL AND DOMESTIC SEWAGE,
T. Stones.
Effluent and Water Treatment Journal, Vol. 23, No. 5, p 206-207, May, 1983. 4 Tab, 9 Ref.

Descriptors: *Wastewater treatment, *Design criteria, Effluents, Industrial wastes, Domestic wastes, Biochemical oxygen demand, Oxygen demand.

The relative strengths of industrial vs domestic sewages have been expressed in terms of various criteria. The anomalies in results are due to differences in the extent of oxidation of the two sewages under the conditions of the various determinations. During the determination of the chemical oxygen demand there is virtually complete oxidation of the carbonaceous matter so that this gives an absolute value for the total carbonaceous oxygen demand and hence provides a basis with which the other criteria can be compared. The 5-days biochemical oxygen demand thus represents 54.2% of the total carbonaceous oxygen demand in the case of the domestic sewage but only 37.2% thereof in the case of the industrial sewage which is relatively 31.4% less, while the permanganate value represents 10.1% of the total carbonaceous oxygen demand in the case of the domestic sewage but 13% thereof in the case of the industrial sewage which is relatively 28.7% more. A substantial amount of the carbonaceous matter present in sewage that is inert to biochemical oxidation under the normal conditions is removed during the course of treatment and so constitutes a significant part of the oxidizable load imposed upon a biological oxidation plant. The use of the 5-day BOD as a basis for determining the capacities of such plants is therefore illogical as it leads to the paradoxical situation in which plants of smaller capacity are thereby calculated as being necessary for the treatment of intractable industrial sewages than for those intended to deal with equal volumes of domestic sewages readily amenable to treatment. RECLAMATION OF WASTEWATER CONSTITUENTS BY ION EXCHANGE; PART I REVIEW OF FLOWSHEETS FOR THE PROCESSES - CONTINUED FROM VOLUME 23 NUMBERS 1, 2 AND 4,
B. A. Bolto, and L. Pawlowski.
Effluent and Water Treatment Journal, Vol. 23, No. 5, p 208-213, May, 1983. 6 Fig, 24 Ref.

Descriptors: *Recycling, *Ion exchange, *Wastewater renovation, Municipal wastes, Dye industry, Industrial wastes, Agricultural wastes, Waste recovery, Regeneration, Minerals, Phosphates, Nitrates, Water reuse.

The concentration of solutions by evaporation produces condensates which may contain several to a few thousand milligrams of solute per liter. An ion exchange method can be used for recycling the chemicals and the water from the condensate. One of the best known examples is the recycling of condensate constituents from the fertilizer industry. The most important factor affecting the economics of ion-exchange methods is the concentration of the regeneration effluent; special columns are used to increase its concentration. The main problem in the system is to ensure uniform flow of the regeneration effluent through the ion-exchange bed. If regeneration effluents containing (NH4)2SO4 are introduced into the processing of ammonium nitrate, the durability of the ammonium nitrate granules is increased which improves their quality as a fertilizer. The removal of nutrients from wastewaters becomes a very important goal to ensure survival of water supplies. An interesting attempt to use ion exchange for the recovery of ammonium and phosphate ion is based on the selective adsorption of ammonium ions on clinoptilolite and of phosphate on an anion exchanger, and on the precipitation of MgNH4PO4 from the regeneration effluent. Another approach uses nitric acid and ammonia to regenerate an ion exchanger bed for the tertiary treatment of effluents. The regeneration effluent, being a mixture of ammonium and nitrate salts, is used as a fertilizer. Ion exchange methods have recently been used in recovering organic compounds from wastes such as the separation of sulfonic and sulfuric acids. In the dyeing of acrylic fibers with cationic dyes, the used dye bath and wash liquors are recycled through a three-column system: activated charcoal followed by two cation exchanger beds in the H-form. Recovered water is recycled. Recovery of water from brackish agricultural and municipal wastewater has also been proposed. The regeneration effluent from ion exchange softening plants can also be reused. (Baker-IVI)

A REVIEW OF ACTIVATED SLUDGE TREATMENT; PART I,
M. S. Ray.
Effluent and Water Treatment Journal, Vol. 23, No. 6, p 225, 227-229 and 231-232, June, 1983. 3 Fig, 5 Tab.

Descriptors: *Activated sludge process, *Wastewater treatment, Oxygen, Oxidation, Unox process, Cost analysis, Bacteria, Aeration tanks, Nitrification, Microorganisms.

A concise summary of the nature of the activated sludge treatment process is presented along with a discussion of the use of pure oxygen for treatment, a description of the Unox process with useful data and associated costs, and the mention of oxygenation systems other than tank-based processes. A wide variety of microorganisms are found in activated sludge including bacteria, filamentous growths, algae and protozoa. There is a favorable range of pH over which bacterial activity is at a maximum, and deviations result in a reduction of efficiency. An aeration system is generally used to dissolve oxygen in the liquid, strip out carbon dioxide, mix aerated liquid and bacterial sludge, and maintain solid matter in suspension. Two major types of systems include the diffused air system and the mechanical aeration system. Potential advantages of the use of oxygen in place of air for activated sludge treatment have been studied. Potential advantages include efficient oxygen dissolution and increased biomass concentration. Potential disadvantages of an oxygen system include the effect of high dissolved oxygen levels, sludge settling rates, excess sludge generation, higher MLSS levels, nitrification, shock loads, bulking, sludge thickening, power consumption, and capital cost. RECLAMATION OF WASTEWATER CONSTITUENTS BY ION EXCHANGE; PART II REVIEW OF CONTACTING EQUIPMENT,
B. A. Bolto, and L. Pawlowski.
Effluent and Water Treatment Journal, Vlo. 23, No. 6, p 233-239, June, 1983. 13 Fig, 25 Ref.

Descriptors: *Recycling, *Waste recovery, *Water reuse, *Ion exchange, Regeneration, Wastewater treatment.

The application of ion-exchange reclamation systems to recycling is considered. Application has historically been divided into moving-bed systems and fixed-bed systems. The moving bed systems may be further divided into cocurrent and countercurrent systems. Countercurrent moving bed systems may be divided into semicontinuous and truly-continuous systems which make use of a compact or fluidized bed. Fixed bed systems may be divided into cocurrent and countercurrent versions, in compact or fluidized bed formats. Another feature which distinguishes the various contacting methods is the sequence and direction of flows through the various process units during loading and regeneration. Use of a moving bed allows one to perform continuous ion-exchange operations which are attractive because of their processing efficiency and their similarity to continuous solvent extraction or distillation. While the fixed bed systems perform reliably in many types of effluent treatments, in the treatment of wastewater one very often has to deal with high turbidity solutions and liquids having a high concentration of solutes. In such cases continuous countercurrent fluidized systems can provide more efficient performance. When the effluent to be treated has a high level of turbidity the CSIRO concept of a continuous apparatus based on magnetic resins can be very useful. The proper selection of contacting equipment for carrying out ion exchange processes in effluent treatment is c

Descriptors: *Biological wastewater treat *Daphnia, *Oocystis, Nutrient removal, Phytoplankton.

Although the effluent from the sewage treat plant is an improvement over untreated eff this discharge is still rich in nutrients which a erate the eutrophication of the collector strea has been proposed that the fertilizer potenti these wastewaters could be used to produce through the controlled growth of phytoplan This study was aimed at examining the possi of using Daphnia magna to recover the pl plankton produced in high concentration du the biological treatment of wastewaters. Inge rate, assimilation rate and assimilation effici were measured for Daphnia grown under trolled experimental conditions in secondary ed wastewaters. The rate of ingestion was hi at 15 C than at 20 C and depended on the con tration of algae (Oocystis sp.) used: 10 and 50 C/l. The rate of assimilation was constant at a 1-8 micro g C per Daphnia per hour. It is prop that the incipient limiting level of ingestion co sponds to the concentration where the assimila rate is maximum. At food concentrations hi than this level of ingestion, Daphnia control m anisms normally maintain a constant ingestion and prevent superfluous feeding. These res however, revealed the inefficiency of these me nisms at high food concentrations, leading Dap to superfluous feeding. Nevertheless, Daphni

tself as a good candidate for the filtration of tis produced in wastewaters. (Moore-IVI) 1590

ELECTRON MICROSCOPIC EXAMINATION OF WASTEWATER BIOFILM FORMATION AND STRUCTURAL COMPONENTS,
New Hampshire Univ., Durham. Dept. of Civil Engineering.
T. T. Eighmy, D. Maratea, and P. L. Bishop.
Applied and Environmental Microbiology, Vol. 45, No. 6, p 1921-1931, June, 1983. 7 Fig, 52 Ref.

Descriptors: *Biofilms, *Wastewater, *Bacteria, Glycocalyx, Matrix, Electron microscopy.

A biofilm is an assemblage of bacterial cells that is both enclosed by and attached to a wetted surface by means of an extracellular fibrous polysaccharide-containing matrix, termed a glycocalyx. In situ wastewater biofilm formation, structure, and physicochemical properties were studied by scanning and transmission electron microscopy. Cationized ferritin was used to label anionic sites of the biofilm glycocalyx for viewing in thin section. Wastewater biofilm formation paralleled the processes involved in marine biofilm formation. Scanning electron microscopy revealed a dramatic increase in cell colonization and growth over a 144-h period. Constituents included a variety of actively dividing morphological types. Many of the colonizing bacteria were flagellated. Filaments were seen after primary colonization of the surface. Transmission electron microscopy revealed a dominant gram-negative cell wall structure in the biofilm constituents. At least three types of glycocalyces were observed. The predominant glycocalyx possessed interstices and was densely labeled with cationized ferritin. Two of the glycocalyces appeared to mediate biofilm adhesion to the substratum. The results suggest that the predominant glycocalyx of this thin wastewater biofilm serves, in part, to enclose the bacteria in a matrix and anchor the biofilm to the substratum and provide an extensive surface area with polyanionic properties. IMPROVED EVAPORATORS FOR RADIOACTIVE WASTES,
Graver Co., Union, NJ. Unitech Div.
D. Anthony.
Chemical Engineering Progress, Vol. 79, No. 7, p 58-63, July, 1983. 3 Fig, 5 Tab, 5 Ref.

Descriptors: *Wastewater treatment, *Radioactive wastes, *Ammonia, *Corrosion, Water reuse, Reclaimed water, Industrial wastes.

Evaporation can be an effective and economical means of treating radioactive waste in the nuclear plant. It reduces the waste volume through evaporation of the volatile solvent (water) resulting in a smaller volume and smaller mass of contaminated material for ultimate storage or disposal. Relatively pure water (condensed vapor), is recovered and can be recycled or reused within the plant or discharge to the environment with little or no additional treatment. One of the largest contributing sources of radwaste in a nuclear plant is the waste effluent produced in the regeneration of ion exchange resins. This waste typically consists of a solution of roughly 1-2% sodium sulfate in water. Difficulties in operating radwaste evaporators have stemmed mainly from corrosion, but new materials are being made which are more corrosion resistant. The chemical regeneration of demineralizer beds is accomplished by passing appropriate chemical solutions through the resin beds. The presence of significant amounts of ammonia and ammonia compounds in evaporator or crystallizer feed streams has recently been found to cause some potentially serious difficulties which can be classified into three categories: distillate quality, solidification considerations, and corrosion problems. To avoid these problems it is necessary to remove the ammonia from the feed before it enters the evaporator. This can be accomplished by raising the feed pH by the addition of NaOh to the feed tank, and processing the feed through a stripping column which removes the volatile ammonia by steam stripping. The system is effective in reducing the feed ammonia concentration by at least a factor of 200. (Baker-IVI)

ACTIVATED SLUDGE TREATMENT OF SYNTHETIC WASTEWATER CONTAINING PENTACHLOROPHENOL,
Cornell Univ., Ithaca, NY. School of Chemical Engineering.
R. U. Edgehill, and R. K. Finn.
Biotechnology and Bioengineering, Vol. 25, No. 9, p 2165-2176, September, 1983. 4 Fig, 2 Tab, 19 Ref.

Descriptors: *Activated sludge process, *Pentachlorophenol, *Wastewater treatment, Industrial wastes, Wood treatment wastes, Pesticides, Wood preservatives, Arthrobacter, Phenols, Shock load.

Treatment of wood products with preservative formulations containing pentachlorophenol (PCP) often results in the generation of polluted effluents, and conventional activated sludge treatment of wastewaters containing PCP is inefficient and unreliable. With a synthetic waste containing some sugars, and 40-120 mg/l PCP, laboratory activated sludge required about seven days for acclimation. The prior addition of a quasipure culture of PCP-metabolizing Arthrobacter resulted in immediate acclimation. Even with acclimated sludge, the system was upset for two days by a simple step change from 40 to 120 mg/l of PCP. The stability of the system to such a shock load was considerably improved when a chemostat culture of the PCP-metabolizing Arthrobacter was fed slowly into the mixed liquor. Kinetic models were developed to describe the dynamic response of the system in terms of growth parameters, hydraulic detention time, sludge age, and bleed-in rate from the chemostat. (Moore-IVI)

FACTORS REGULATING THE DENSITY OF BACTERIA IN PROCESS WATERS OF A PAPER MILL,
Helsinki Univ. (Finland). Dept. of Microbiology.
P. Vaatanen, and S. I. Niemela.
Journal of Applied Bacteriology, Vol. 54, No. 3, p 367-371, June, 1983. 4 Tab, 8 Ref.

Descriptors: *Pulp and paper industry, *Process water, *Bacteria, Klebsiella, Acinetobacter, Pseudomonas, Water temperature, Hydrogen ion concentration, Redox potential, Finland.

Variations in the numbers of total colonies of Klebsiella pneumoniae, Acinetobacter spp. and pseudomonads were investigated in process waters of a paper mill in southern Finland. Variations were related to independent parameters, namely temperature, pH, redox potential and production of offset paper, by using multiple regression analysis. Temperature was the most significant regressor variable and was negatively correlated with bacterial counts. It accounted for up to about 80% of the variance in bacterial counts in various parts of the process. The significance of temperature was due to its fluctuations in a critical range, above and below the maxima for bacterial growth. The pH level was also significant for total colony count and for K. pneumoniae. Redox potential and the production of offset paper were of significance for

Acinetobacter spp. Washing the paper machine with water and lye decreased the numbers of bacteria in process waters. (Author's abstract)

5E. Ultimate Disposal Of Wastes

LAND TREATMENT OF HAZARDOUS WASTE,
A. Morrison.
Civil Engineering, Vol. 53, No. 5, p 33-38, May, 1983. 1 Fig, 3 Tab.

Descriptors: *Waste disposal, *Land disposal, *Organic compounds, Oils, Pesticides, Solvents, Inorganics, Hazardous materials, Waste management, Monitoring.

Land treatment, or land cultivation, is both controversial and promising. The controversy stems from the poor state of knowledge about the fate and transport of chemicals, especially hazardous ones, in the soil. In land treatment selected wastes are applied to a topsoil layer where they are broken down organically or immobilized. At some sites wastes were flood-irrigated onto the soil then allowed to dry. There are roughly 200 land treatment sites in operation, over 100 of them at refineries and almost all of them used by industrial concerns needing to dispose of their own wastes. Testing must be done to determine the suitability of the wastes before instituting operation of the system. Monitoring systems must be designed to determine the condition of the groundwater and the soil in the unsaturated zone beneath the treatment zone. In order for this management intensive process to function it is important to determine what types of wastes and what amounts are able to be so treated. Organics are probably better candidates for land treatment than inorganics. Particularly suitable are solvents, pesticides, and oils. System failure may result if wastes containing highly resistant or mobile compounds are applied as they may leach to the groundwater through a permeable soil layer. The most important of the EPA land regulations is that a demonstration pior to facility start up must be performed. (Baker-IVI)

MUTAGENICITY OF MUNICIPAL SEWAGE SLUDGES OF AMERICAN CITIES,
New York State Coll. of Veterinary Medicine, Ithaca. Dept. of Preventive Medicine.
J. G. Babish, B. E. Johnson, and D. J. Lisk.
Environmental Science Technology, Vol. 17, No. 5, p 272-277, May, 1983. 2 Tab, 26 Ref. 507 RR05462.

Descriptors: *Sludge, *Mutagenicity, Industrial wastes, Wastewater treatment, Chemical treatment, Municiple wastes.

Dichloromethane extracts of sludge samples from 34 cities were tested for mutagenicity by using the Salmonella/mammalian microsome assay. Of the 34 samples, 33 demonstrated a dose-related increase in revertants in at least 1 of the 5 tester strains; of these 33 samples, 12 were positive with 2 or more strains. Seventy-six percent of the positive samples required metabolic activation to demonstrate mutagenicity, while 18% were mutagenic with and without the S-9 fraction, and 6% were mutagenic only in the absence of any metabolic activation. No association existed between the independent variables percent industrialization, wastewater treatment scheme, and chemical additives when tested individually against mutagenicity. WASTE SLUDGE TREATMENT - MORE PERFORMANCE FOR LESS MONEY,
J. Warden.
Effluent and Water Treatment Journal, Vol. 23, No. 4, p 140-143, April, 1983. 3 Fig.

Descriptors: *Sludge thickening, *Hydroxide, Sludge disposal, Wastewater treatment, Polymers.

When raw water is dosed with coagulant the coagulant hydroxide is precipitated. This precipitate forms loose, open floc structure which accumulates on the filter, necessitating backwashing to clean the system. Coagulant hydroxide is exceedingly difficult to dewater, and it arises at very low concentrations, averaging about 0.08% by weight. With polyelectrolites it is possible to form large flocs which settle rapidly and achieve a high rate of solids capture. When dosed into a sludge the polymer acts very rapidly. If the flocs are very small when the polymer is dosed, the long polymer chain molecules will link across and round them. This is done in practice by pumping the flow through an orifice plate to make the flocs very small just at the point where the polymer is dosed. The sludge produced was described as containing no free water because if it was left standing for several hours it did not thicken any more and no free water appeared on the surface. It appeared that all the water which could be removed had been squeezed out by the kneading action of the thickener rake. Between 1 and 2 parts of polymer was used per thousand parts of sludge solids by weight. The first plant to use this technology was commissioned in January of 1980. The waterworks produced 2 million gallons daily and the solids load is about 450 lb/day. The works effluent at about 0.3% solid is retreated in a 5 ft diameter continuous thickener at a polymer cost of less than 50 pence per day and dewatered in a small hand operated filter press on a 4 hr cycle, two pressings per day. OPERATIONAL EXPERIENCE USING H2O2 IN LANDFILL LEACHATE TREATMENT,
Interox Chemicals Ltd., Widnes (England).
J. A. L. Fraser, and N. Tytler.
Effluent and Water Treatment Journal, Vol. 23, No. 4, p 149-156, April, 1983. 2 Fig, 6 Tab, 19 Ref.

Descriptors: *Leachates, *Landfills, *Hydrogen peroxide, *Odor control, Waste dumps, Groundwater contamination, Lagoons, Sulfates, Bacteria, Seasonal variations, Cost analysis, England.

Some of the techniques employed in gaining control of a leachate problem at the Bray-on-Thames landfill site are reviewed. The site consists of a single large quarry bounded on three sides by residential development. The central area is subdivided into lagoons which have been used for storage of contaminated water comprising raw and diluted leachate originating from the worked and reclaimed areas. Principal objectives of the restoration included the control of sulfide odor emission from lagoon surfaces; improvement in the leachate quality sufficiently to meet the discharge criteria imposed by the Thames Water Authority; implementation of remedial site engineering to seal the surrounding perimeter ditch and stem ground water ingression; removal of misplaced land drains and re-alignment of surface contours over reclaimed areas to control leachate production and improve surface runoff. Seasonal variations in quality and quantity of leachate had to be considered as well as making every effort to expend only minimal capital costs for dosing equipment. Heavy duty, portable, diesel engines, vacuum primed pumps were chosen to move the leachate mass. Sulfide odors were controlled using a well-tried technique of surface treatment calling for placement of containers of peroxide every 20 m along the upwind banks of lagoons and allowing peroxide to drip into the water at 100 ml/min. Descriptors: *Activated alumina, *Water t ment, Drinking water, Adsorption, Regenera Wastewater treatment, Activated carbon, Coa tion, Polymerization, Organic compounds.

At present activated alumina cannot substitute activated carbon. However the specific adsorp and ease of regeneration of activated alu makes it a material worthy of deeper study. Po ising applications now being investigated inc the possibility of specific activation during pr ration and use in combined processes with ca or oxidation. For waste water it is possible aluminas which are less high grade materials activated carbons could find useful applica Activated aluminas are classified by temperat origin, and ,crystalline structure. The capacit remove mineral constituents is reported, an summary is given of the basic aspects of the moval of organics. In this latter case the s reported from the literature concludes that ads tion on alumina is complementary to that carbon because there is specific adsorption of p substances and those of high molecular we ease of regeneration by heat or by oxidation the possibility of surface action involving coag tion, adsorption and polymerization. Adsorp isotherms are given for activated alumina for cyclic acid, and octylbenzene sulfonate. It found difficult to compare these results with th for activated carbon but an isotherm for adsorp of benzoic acid on carbon is given. (Moore-I W84-01459

Model studies.

The WATerMANagement model (WATMAN) was expanded for application to small water systems serving populations of 100-10000 so that the economics of alternative solutions to meeting new water quality standards can be evaluated. Two hypothetical cases and two actual situations were tested with the model to select preferred water supply options. In all four cases, the WATMAN model identified cost-effective solutions and competitive alternatives through a present-value analysis. The ability of the model to incorporate site-specific characteristics, to develop preliminary designs, and to make economic estimates for individual communities was demonstrated. (Moore-IVI)

TETRACHLOROETHYLENE LEACHED FROM LINED ASBESTOS-CEMENT PIPE INTO DRINKING WATER,
Environmental Protection Agency, Boston, MA. Water Supply Branch.
C. D. Larson, O. T. Love, Jr., and G. Reynolds, III.
Journal of the American Water Works Association, Vol. 75, No. 4, p 184-188, April, 1983. 5 Fig, 2 Tab, 2 Ref.

Descriptors: *Pipe linings, *Tetrachloroethylene, Leaching, Water distribution, Vinyl toluene liners, Flushing, Continuous bleeders, Drinking water, Water pollution sources.

Tetrachloroethylene has been detected in concentrations ranging from a few micrograms per liter to several milligrams per liter in dead ends of water distribution systems made of vinyl-toluene-lined asbestos-cement pipe. About 1600 km (1000 mi) of this lined pipe is being used, primarily in New England. Tetrachloroethylene concentrations can be lessened by flushing and installing continuous bleeders, two of the solutions being suggested to correct this organics problem, which resulted from steps to control corrosion of asbestos-cement pipe. VARIATIONS IN PARTICULATE MATTER, ALGAE, AND BACTERIA IN AN UNCOVERED, FINISHED-DRINKING-WATER RESERVOIR,
Association of Bay Area Governments, Berkeley CA.
G. S. Silverman, L. A. Nagy, and B. H. Olson.
Journal of the American Water Works Association, Vol. 75, No. 4, p 191-195, April, 1983. 1 Fig, 3 Tab, 30 Ref.

Descriptors: *Drinking water, *Finished-water reservoirs, *Water quality, Particulate matter, Algae, Bacteria, Turbidity, Chlorination, Particle size, Coliforms, Copper, Iron.

Physicochemical and microbiological analyses were performed on influent and effluent samples taken from Garvey Reservoir (Los Angeles County, California). Data collected on particle counts and size distributions, total plate count, coliform bacteria, algal counts, chlorophyll, turbidity, copper, and iron were analyzed with a computerized statistical package. The quality of the influent was degraded through biological activity in the reservoir to produce a lower-quality effluent. Results indicated that algae were associated with increased turbidity and particulate levels and might enhance or support bacterial activity, including physical protection of bacteria against the effects of chlorination. FREE CHLORINE VERSUS AMMONIA-CHLORINE: DISINFECTION, TRIHALOMETHANE FORMATION, AND ZOOPLANKTON REMOVAL,
R. P. Mitcham, M. W. Shelley, and C. M. Wheadon.
Journal of the American Water Works Association, Vol. 75, No. 4, p 196-198, April, 1983. 3 Fig, 6 Tab, 2 Ref.

Descriptors: *Chlorination, *Disinfection, Ammonia-chlorine, Residual chlorine, Trihalomethanes, Zooplankton, Copepods, Cladocera, Water treatment, Halogenated hydrocarbons.

The relative efficiency of ammonia-chlorine and free residual chlorine in the treatment of lowland river water was studied. The roles of these chemicals in trihalomethane (THM) formation, water disinfection, and zooplankton removal were considered. Use of ammonia-chlorine reduced THM formation by as much as 80% and did not impair water disinfection. Compared with free residual chlorine, ammonia-chlorine was more effective against Copepoda (Cyclops) but less effective against Cladocera (Daphnia and Bosmina). (Author's abstract)

TREATING SURFACE WATERS FOR COMMUNITIES IN DEVELOPING COUNTRIES,
United Nations Development Programme, Washington, DC. Interregional Program.
C. R. Schultz, and D. A. Okun.
Journal of the American Water Works Association, Vol. 75, No. 5, p 212-219, May, 1983. 7 Fig, 1 Tab, 7 Ref.

Descriptors: *Water treatment, *Developing countries, Coagulation, Surface water, Economic aspects, Water treatment facilities, Maintenance, Operating costs.

Water treatment plants in developing countries should use simplified technologies that require little automation or mechanization to lower capital costs significantly. Operations and maintenance should also be less costly and more suitable for local labor conditions. Only as a last resort should chemical coagulation and rapid filtration be adopted. Mechanical equipment should be limited as much as possible to that produced locally. Hydraulic devices that use gravity are preferred over motor-driven equipment. The plant must be designed to treat the raw water available. Use can be made of natural coagulants derived from plants and animals to reduce the cost of treatment. Coagulation aids are effective at high turbidity levels, with possible savings of 40-50% in alum consumption. (Moore-IVI)

SIMPLIFYING DESIGN OF WATER TREATMENT PLANTS FOR DEVELOPING COUNTRIES,
Water and Air Research, Inc., Gainesville, FL.
E. G. Wagner.
Journal of the American Water Works Association, Vol. 75, No. 5, p 220-223, May, 1983. 1 Tab, 1 Ref.

Descriptors: *Water treatment facilities, *Developing countries, Economic aspects, Water treatment, Operating costs.

In the developing world, there is an acute shortage of money, managerial and technical skills, skilled labor, and well-organized, stable institutions. Therefore, water treatment plants in developing countries should be low in first cost and easy and economical to operate. The development of this kind of plant begins with a search for the best water source, includes determining the most effective treatment process, and continues through designing the plant. In water treatment plant design, there must be a conscious effort to minimize equipment, to maximize the use of gravity and hydraulics in the treatment process, and to make use of labor rather than equipment in the operation of the plant wherever possible. PREOZONATION AS A COAGULANT AID IN DRINKING WATER TREATMENT,
Saunier Eau et Environnement, St. Gregoire (France).
B. M. Saunier, R. E. Selleck, and R. R. Trussell.
Journal of the American Water Works Association, Vol. 75, No. 5, p 239-246, May, 1983. 16 Fig, 5 Tab, 6 Ref.

Descriptors: *Ozonation, *Flocculation, Water treatment, Basic aluminum chloride, Turbidity, Particulates, Chemical oxygen demand, Sedimentation.

The effects of preozonation on the treatment of Seine River water were evaluated in a pilot plant consisting of flocculation with basic aluminum polychloride (PAC) followed by sedimentation. Preozonation significantly increased the removals of turbidity, particle numbers and volumes, chemical oxygen demand, and UV absorbance at all treatment levels investigated (0.3-1.2 mg/L for ozone, and 15-60 mg/L for PAC), with the optimum ozone dose appearing to be about 0.8 mg/L. The favorable effects of ozone increased with pH and the particle count of the untreated water. The increases in particle removals appeared to stem partly from increases in floc size and settling velocity. (Author's abstract)

USING BY-PRODUCTS OF AN IRON REMOVAL PROCESS TO IMPROVE WATER TREATMENT,
Curry and Associates Engineers, Inc., Nashville, IL.
M. D. Curry, and M. Reynolds.
Journal of the American Water Works Association, Vol. 75, No. 5, p 246-248, May, 1983. 2 Fig, 3 Tab, 7 Ref.

Descriptors: *Water treatment, *Iron, *Manganese, Oxidation, Coagulation, Backwash reclamation, Corrosion, Hydrogen ion concentration, Potassium permanganate, Ferric hydroxide.

A conventional treatment for removing iron and manganese from groundwater was used by the village of Roxana, Ill., but the process did not reduce concentrations of these metals to recommended maximum levels. After using temporary measures, the village began looking at several long-term alternatives to solve the water quality problems. Of the alternatives considered, oxidation and removal of manganese with potassium permanganate was investigated further in bench studies. Modification of full-scale treatment effected the removal of manganese by using permanganate feed, ferric hydroxide from the reaction basin as a primary coagulant, and a cationic polymer as a coagulant aid. Reclamation of backwash eliminated a potential problem with disposal of the backwash. Both manganese and iron were reduced to acceptable levels. In addition, the increase in pH helped decrease corrosive water conditions in the distribution system, and the duration of filter runs was lengthened. (Author's abstract)

REMOVING NONVOLATILE ORGANIC CHLORINE AND ITS PRECURSORS BY COAGULATION AND SOFTENING,
Los Angeles County Sanitation Districts, Whittier, CA.
D. E. Johnson, and S. J. Randtke.
Journal of the American Water Works Association, Vol. 75, No. 5, p 249-253, May, 1983. 9 Fig, 5 Tab, 26 Ref. NSF-ENG-7908187.

Descriptors: *Chlorinated hydrocarbons, *Coagulation, *Water softening, Chlorination, Water treatment, Organic matter, Alum, Lime, Fulvic acid, Total organic chlorine, Chloroform, Hydrogen ion concentration.

Chlorine added to a potable water supply for disinfection will react with naturally occurring and anthropogenic organic matter present in the water to form volatile and nonvolatile halogenated organic by-products that represent a potential health hazard. In order to evaluate the potential of conventional water treatment to remove nonvolatile organic chlorine and its precursors, samples of groundwater, surface water, secondary effluent, and fulvic acid were treated in laboratory experiments by alum coagulation and lime softening in conjunction with prechlorination and postchlorination. Coagulation and softening both removed significant amounts of nonvolatile organic chlorine, precursors of organic chlorine, and total organic carbon (TOC). Organic chlorine precursors were removed as well as or better than TOC and much better than the organic chlorine formed during prechlorination. The increase in pH during lime treatment hydrolyzed a significant fraction of the nonvolatile organic chlorine, releasing chloroform and other by-products. (Moore-IVI)

USING BACKWASHING KINETICS TO EVALUATE ATTACHMENT MECHANISMS AND FORCES DURING FILTRATION,
SWEHELL Co. Ltd., Athens (Greece).
G. Toregas.
Journal of the American Water Works Association, Vol. 75, No. 5, p 254-260, May, 1983. 8 Fig, 3 Tab, 6 Ref.

Descriptors: *Filtration, *Coagulation, Backwash, Kinetics, Deep-bed filtration, Alum, Particle size, Mathematical models, Particle agglomeration, Filters.

A method is offered for evaluating the various models involved in particle removal from water by means of deep-bed filtration. Based on backwashing kinetics, this method takes into account the mechanisms associated with particle attachment (with and without alum treatment), particle agglomeration, and particle detachment. When the particle to grain size ratio (dp/dm) is greater than 0.055 straining appears to be important. For dp/dm ratios between about 0.040 and 0.055, straining appears to be significant; at dp/dm ratios below about 0.040, straining apears to be insignificant. The contribution of particle-medium interactions to the overall filter deposit was about constant (35% of total particle removal), whereas the contributions of the particle-particle interactions appears to depend on whether straining is significant. For filtration to be effective, particle-particle interactions should be predominant (accounting for as much as 65% of the total particle removal). The relative magnitude of attachment forces associated with collisions between particles and filte
and with the formation of agglomerates
from alum treatment prior to filtration was
ed by using backwashing recovery data.
tachment force acting during formation o

Descriptors: *Water treatment, *Conc
Resins, Contamination, Design criteria,
plants, Water quality control, Cooling wate

Condensate polishing refers to the purific
power station turbine condensate to ensure
ed water quality which is acceptable as fee
to modern high pressure steam plants in th
generation industry. The main danger is the
of cooling water into the condensate. This
major problem as a condenser ages due to
or corrosion, bringing about pinhole perf
in the tube material. A second source of
sate contamination can be due to maloper
the power station make-up plant, permittin
rectly treated make-up water into the feed
A further problem may be the solution of
pheric carbon dioxide in the feed water
tanks. Soluble impurities may also be pres
lishing equipment is to remove both solu
insoluble impurities. The tendency is to
mixed bed deionization process, comprise
intimate mixture of cation and anion e
resins. The avoidance of regenerant cross c
nation is a matter of engineering design. It i
undesirable to introduce chemical regenera
a turbine room because of the danger o
feed-line contamination. Because high flo
are used in the condensate polishing proc
bed depth has to be limited in order t
pressure loss across the plant is maintain
satisfactory value. The degree of resin cr
tamination is very much influenced by cha
resin charge volume. Such changes mean
cation/anion interface level after separatio
in respect to the level of the anion resin
point and sluicing jet position. To solve th
lem of resin cross contamination, Kennicot
oped the Consep system, in which a ve
degree of resin separation is achieved. (Bak

*Ultraviolet radiation, *Sodium sulfite,
treatment, Filtration, Pilot plant, Municipal
Toxicity, Chlorine, Halogenated hydrocarbo

Many research facilities rely on municipal
supplies as a source of dilution water for
toxicity investigations or for rearing and s
aquatic organisms, but chlorine, common
ployed as a disinfectant, is highly toxic to
freshwater organisms. The characteristics o
dechlorination by activated carbon filtratio
irradiation and sodium sulfite injection were
ined. A pilot plant water treatment systen
posed of sand and diatomaceous earth fil

tion and activated carbon filtration was eval-
Activated carbon did not completely elimi-
chlorine under any conditions tested but the
arbon chlorine concentrations were relative-
ensitive to large variations in incoming chlo-
evels and water flow rates. Carbon filtration
educed total dissolved organic carbon con-
tions by 65% and reduced various haloge-
methane derivatives by 97-100%. Ultraviolet
tion eliminated up to 99% of the total chlo-
municipal water but u.v.-dechlorination was
ve to flow rate with a rate constant of 2.02/
etween 10 and 271/min. Water temperatures
g from 7.5 to 20.6 C did not affect the
ncy of dechlorination by activated carbon or
radiation. Sodium sulfite at a 3:1 molar ratio
lorine completely eliminated chlorine from
ipal water while a sulfite:chlorine ratio of 6:1
equired to completely dechlorinate water
had been partially dechlorinated by activat-
bon. (Moore-IVI)

Water Quality Control

ATE IN BRITISH WATERS,
al Water Council, London (England).
White.
No. 2, p 51-57, April, 1983. 6 Fig, 27 Ref.

ptors: *Nitrate, *Water quality control,
Britain, Standards, Water pollution sources,
ng water, Human diseases, Methemoglobin-

risks and water quality standards are dis-
for nitrate. The origin of nitrate in water is
ed as a background to rising concentrations
n rivers and groundwater. The identified
risk which was noted in the 1974 IWSA
tional Standing Committee on Water Qual-
l Treatment Report was methemoglobine-
nce that time the incidence of this problem
come rarer in Great Britain. Nitrate concen-
trations in both rivers and groundwater sources have been increasing and the problems could become worse before equilibrium is reached. The principal cause is changes in farming practices to enhance agricultural productivity. Opportunities for controlling nitrate sources are limited. Water treatment processes have been developed with a view to keeping nitrate concentrations in public supplies below 50 mg/l NO3. The viability of ion exchange has been established and problems in biological denitrification are being overcome. There is a possibility of substantial expenditure being required to reduce nitrate concentration but steps to deal with the problems in public supplies are well in hand. In Britain about 99% of the population receives water from the public supply systems. The most significant risks attached to nitrate lie with the small minority who rely on private supplies from shallow wells. (Baker-IVI)

NITRATE IN THE NETHERLANDS - A SERIOUS THREAT TO GROUNDWATER,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands).
W. V. Duyvenbooden, and J. P. G. Loch.
Aqua, No. 2, p 59-60, April, 1983. 1 Tab, 4 Ref.

Descriptors: *Nitrate, *Groundwater pollution, Water quality, Netherlands, Agricultural runoff, Soil properties, Drinking water, Fertilizers.

A nitrate problem exists in the Netherlands, in the sandy regions of the country located in the eastern and southern parts. Nitrate concentrations in the groundwaters are gradually rising, primarily due to agricultural activities. Particular in the bio-industrial areas, extremely high nitrate levels are found, extending deeply where there are aerobic conditions. A gradual deterioration has been detected in the quality of the groundwater. Without special measures being taken it is expected that in many cases nitrate levels in groundwater will in the long run rise above the European standards for drinking water. Serious attention will have to be given to measures to secure the supply of groundwater of a sufficient quality with respect to nitrate. At present no national regulations exist on the use of manure and fertilizers to protect groundwater. Some regional regulations have in principle the possibility of restricting the use of nitrogen in the protection zones around groundwater pumping stations, but in practice these rules are seldom complied with. NITRATE IN WATERS FOR HUMAN CONSUMPTION: THE SITUATION IN FRANCE (1979-1981). A STUDY BY THE FRENCH MINISTRY OF HEALTH, (TENEUR EN NITRATE DES EAUZ DESTINEES A LA CONSOMMATION HUMAINE: LA SITUATION EN FRANCE (1979-1981). ETUDE REALISEE PAR LE MINISTERE DE LA SANTE FRANCAIS: CADRE DE L'ETUDE).
Aqua, No. 2, p 74-78, April, 1983. 2 Fig, 7 Tab.

Descriptors: *Nitrates, *Groundwater, *Drinking water, *Regulations, France, Agricultural runoff, Well water, Groundwater contamination.

The French Ministry of Health has issued instructions on the attitude to be taken in regard to the presence of nitrate in drinking water. A survey was performed which revealed that 81% of the population has nitrate levels less than 25 mg/l and 96% to 98% has levels less than 50 mg/l in their drinking water supplies. Out of 53 million people approached in the survey, 280,000 at most have a water supply which exceeded 100 mg/l of nitrate at least once in the last three years. Out of the 20,000 distribution units surveyed about 1000 had nitrate above 50 mg/l and 61 only were about 100 mg/l. Most of the high nitrate areas were in the North and West of metropolitan France. Most of the high nitrates are found in groundwater, and most of the wells affected were in highly developed agricultural areas. Treatment by activated carbon is very effective but costly particularly because of regeneration whose frequency depends on speed of saturation of the carbon and thus on its place in the sequence of treatment. Based on a study of the physical chemical characteristics of aluminas suitable for industrial use, it is concluded that activated alumina cannot fulfil the role of activated carbon for drinking water quality control. However, because of the specific adsorption capacity and the ease of regeneration the use of activated alumina for the removal of organics is a subject which must be pursued. The possibility of specific activation during alumina preparation or alumina-carbon methods or alumina in oxidation treatment should be considered. (Baker-IVI)

INTERACTION OF CLAY SOILS WITH WATER AND ORGANIC SOLVENTS: IMPLICATIONS FOR THE DISPOSAL OF HAZARDOUS WASTES,
Texas Tech Univ., Lubbock. Dept. of Civil Engineering.
W. J. Green, G. F. Lee, R. A. Jones, and T. Palit.
Environmental Science and Technology, Vol. 17, No. 5, p 278-282, May, 1983. 4 Fig, 2 Tab, 13 Ref.

Descriptors: *Clays, *Land disposal, *Hazardous materials, Waste disposal, Organic solvents, Partition, Interstitial water, Soil dehydration, Clay liners.

Studies of the behavior of three compacted, moist clay soils when immersed in water and in organic solvents have been conducted. The correlation between the logarithm of the octanol-water partition coefficient (log Kow) and the percent swelling of the clay soil suggests that swelling in these systems depends upon the transfer of immersion fluid into the clay soil pore waters. X-ray diffraction data obtained on air-dried clay soils treated with various liquids indicate that interlayer expansion does not occur in these systems. Slight shrinkage of clay soils in apolar, hydrophobic solvents such as carbon tetrachloride and xylene indicates that these liquids could damage the integrity of clay liners used for hazardous waste disposal pits. On the basis of these results, it is recommended that laboratory shrink-swell testing be conducted on samples of clay liners and representative waste mixtures and soils of the type to be encountered at a storage site. ORGANIC MICROPOLLUTANTS IN WATER - A WHO VIEWPOINT,
J. I. Waddington.
Effluent and Water Treatment Journal, Vol. 23, No. 4, p 145-148, April, 1983. 1 Tab, 10 Ref.

Descriptors: *Hazardous materials, *Organic compounds, Toxicity, Quality control, Water quality, Guidelines, Regulations.

An increasing number of organic micropollutants are reaching the aquatic environment via sewage treatment plants and from industrial and agricultural activities. For many years the World Health Organization (WHO) has been developing health criteria related to the toxicity of chemical substances. Absolute safety is an impossible goal in relation to any aspect of life and a careful approach to risk assessment, cost-benefit and priority setting must be adopted if the major problems are to be satisfactorily overcome. The relationship between exposure and the spectrum of effects is referred to as the dose-response and an understanding of this relation constitutes a base for the study of toxicity. Dose-response curves have been developed for many chemicals, permitting the development of acceptable daily intakes (ADI) based on the non-observable adverse effects (NOAE) level. A problem with this approach lies with the duration of the NOAE level. There is uncertainty as to how long

such an intake can be tolerated without subsequent damage being sustained. (Baker-IVI)

EFFECT OF LOW LEVELS OF EXCHANGEABLE SODIUM AND APPLIED PHOSPHOGYPSUM ON THE INFILTRATION RATE OF VARIOUS SOILS,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Inst. of Soil and Water.
Z. Kazman, I. Shainberg, and M. Gal.
Soil Science, Vol. 135, No. 3, p 184-192, March, 1983. 6 Fig, 1 Tab, 14 Ref.

Descriptors: *Infiltration rate, *Sodium, *Soil crust, Arid regions, Lime, Phosphogypsum, Rain, Soil surface, Calcium carbonate, Soil solution, Electrolytes, Soil aggregates, Soil chemistry, Israel.

The arable soils in the arid and semiarid regions of Israel contain 2 to 6% exchangeable sodium in the upper layer. Considerable amounts of runoff and erosion from these soils, measured during rainstorms, have been associated with aggregate dispersion and crust formation at the soil surface. The effect of exchangeable sodium percentage (ESP) on the infiltration rate (IR) and crust formation of four soils, varying in their texture, mineralogy, and CaCO3 content was studied, using distilled water (EC approximately .05 mmho/cm) in a rain simulator. The IR of the four soils was very sensitive to low levels of ESP (5), whereas the hydraulic conductivity (HC) of these soils was less sensitive. The presence of lime in the soils was effective in preventing HC decreases due to low levels of exchangeable Na. Conversely, lime was not effective in maintaining the IR of the calcareous soils. Phosphogypsum prevented the sharp drop in IR of the soils at all levels of ESP. The mechanical impact of the raindrops, the low concentration of electrolytes in the rain and in the surface soil solution, and the relative freedom for particle movement at the soil surface accounts for the higher susceptibility of the soil surface to exchangeable Na. The high rate of dissolution of phosphogypsum, leading to the presence of electrolytes in the surface soil solution, accounts for the effectiveness of phosphogypsum in maintaining the high IR. The effect of low levels of ESP and the soil solution concentration of the IR of soils suggests that crust formation in soils is due to two mechanisms: a physical dispersion of soil aggregates caused by the mechanical impact of the raindrops; and a chemical dispersion caused by the soil ESP and the low electrolyte concentration in the applied water. THE INFLUENCE OF THE INITIAL WATER CONTENT ON THE REDISTRIBUTION OF SOIL WATER AFTER INFILTRATION,
Agricultural Coll. of Athens (Greece). Lab. of Agricultural Hydraulics.
A. Poulovassilis.
Soil Science, Vol. 135, No. 5, p 275-281, May, 1983. 5 Fig, 15 Ref.

Descriptors: *Soil water, *Infiltration, *Redistribution, Wetting boundary, Drying boundary, Hysteresis loop.

The effect of the initial soil water content prevailing in a porous column before the initiation of an infiltration-redistribution cycle on the redistribution rate was studied both theoretically and experimentally. The initial water content may vary following either the drying boundary or the wetting boundary curve of the hysteresis loop involved in the infiltration-redistribution process. The redistribution rate for initial states on the drying curve is greater than that for states on the wetting boundary curve. An increase of the initial water content along the drying curve may result in an increase of the redistribution rate, though an increase along the wetting curve may result in a decrease of the redistribution rate. The development of the redistribution pressure head profiles was followed in a 55 cm long tube packed uniformly with beach sand to give a porous body characterized by the hysteretic relationships between soil water content and pressure head. The experimental results support the theoretical conclusions. (Moore-IVI)

THE ROLE OF AIR AND WATER RESIDUALS FOR STEAM ELECTRIC POWER GENERATION,
North Carolina Univ. at Chapel Hill. Dept. of Economics.
N.-B. Tran, and V. K. Smith.
Journal of Environmental Economics and Management, Vol. 10, No. 1, p 35-49, March, 1983. 3 Tab, 39 Ref.

Descriptors: *Water pollution control, *Steam electric powerplants, *Cost analysis, Electric power industry, Regulation, Policy, Industrial wastewater, Effluent, Economic aspects, Mathematical models.

An attempt was made to treat atmospheric and waterborne residuals as joint outputs with electricity in modeling the ex post production technology for steam generating electric power plants. Using a joint output cost function, the findings support the inclusion of these measures in the cost functions for all vintages of the power plants. They suggest that the residual outputs cannot be treated as separable from the variable inputs with any of these vintages. Measured input substitution in previous studies may not accurately reflect the features of the expost technology. These findings also have direct implications for policy concerns. The control of atmospheric and waterborne residuals will necessarily affect the optimal allocation of factor inputs. This suggests that the ex post technology for steam electric generation embodies a response pattern to environmental regulation that is similar to that of ex ante design analyses: in both cases, it can be expected that the adjustments to environmental controls will not be neutral in their effects on factor input usage. Of course, there are likely to be substantial differences between ex ante and ex post technologies in the actual nature of these effects. (Moore-IVI)

POLLUTION CONTROL AND INPUTS TO PRODUCTION,
Tennessee Technological Univ., Cookeville. Dept. of Management, Marketing and Economics.
K. W. Ketkar.
Journal of Environmental Economics and Management, Vol. 10, No. 1, p 50-59, March, 1983. 1 Fig, 1 Tab, 11 Ref.

Descriptors: *Water pollution control, *Industrial wastwater, *Cost analysis, Labor, Capital, Chemical industry, Electrical industry, Oil industry.

The inputs required for air, water, and solid waste pollution abatement in the United States are identified. Industry level data on pollution abatement expenditures in 1976 are broken down into expenditures on various intermediate inputs and on two primary inputs - labor and capital. The 1971 input-output table is adjusted to reflect the input needs of pollution abatement technology. This revised direct input coefficients matrix is used to derive the gross output and primary input requirements of the 1971 final bill of goods. Pollution abatement technology requires inputs from some industries such as chemicals, electricity, and petroleum products, which are highly polluting. This implies that in the process of abating pollution, more pollution will be generated. By using the adjusted input-output matrix, the effect of current (operating) pollution abatement expenditures on the gross outputs of polluting industries, industries supplying inputs for pollution abatements, and other industries are determined. Directly and indirectly roughly 124,000 new jobs would be created per 1 billion dollars of direct pollution abatement expenditure. (Moore-IVI)

OPTIMAL INVESTMENT TO REDUCE THE DECAY RATE OF AN INCOME STREAM: THE CASE OF SOIL CONSERVATION,
California Univ., Davis. Dept. of Agricult Economics.
R. A. Collins, and J. C. Headley.
Journal of Environmental Economics and Man ment, Vol. 10, No. 1, p 60-71, March, 1983. 4 4 Tab, 11 Ref.

Descriptors: *Soil conservation, *Investm *Farming, Soil management, Erosion, Costs, S dies, Capital, Iowa.

Some natural resource investments are unique f a capital theory point of view because they do create a new income stream, but rather alter rate of change of an existing stream of incom social benefit. A firm level model is presented choice of optimal expenditures for soil conse tion capital. The model suggests that the opti decay rate of income due to soil loss depend current farm income, the interest rate, and the effectiveness of soil conservation capital. I from southern Iowa were used to demonstrate farmers in the same area may rationally beh differently when faced with a government sub program for conservation. The model gives a b for calculating the private internal benefits of conservation capital and, therefore, a basis for dicting behavior. (Moore-IVI)

MANAGING RAFTING RIVERS,
Abt Associates, Inc., Cambridge, MA.
D. Berry, C. Cox, and P. Wolff.
Water Spectrum, Vol. 15, No. 1, p 10-17, Spring, 1983. 5 Fig, 2 Tab.

Descriptors: *Recreation demand, *Water use, *Water management, *Rafting, Wilderness, Recreation facilities, Environmental effects, Aesthetics.

In the northeast, conflicts are now arising from large-scale rafting and these are beginning to face recreation and natural resource agencies. This is especially true considering the prevalence of rafting on scenic rivers in primitive woodland environments. Management considerations fall roughly into five categories: launch and take-out characteristics which determine the number of launches which can effectively be handled by a site in a given period of time; launching hours, determining the number of launches which can be made in a given day; number of raftable days, determined by numbers of weekend days and holidays which fall during the rafting season; lunch or break site factors, which are determined by the number of launches being made from one point during the day; and conflicts with other activities such as anglers, canoeists, campers, and with traffic on the roads near the river. Management strategies call for the adoption of a river recreation management plant, the application of land use controls along the river, the imposition of use limits, the requirement of obtain access or other permits, the certification of guides and imposition of safety requirements, and the control of river flow. In order to manage effectively, those responsible for management must have a solid data base documenting point of congestion, environmental damage, conflicts with other recreation activities, and detraction from the aesthetic aspects of rafting by crowding. CAPACITY EXPANSION MODEL FOR LARGE-SCALE WATER-ENERGY SYSTEMS,
International Engineering Co., Inc., San Francisco, CA.
J. Matsumoto, and L. W. Mays.
Water Resources Research, Vol. 19, No. 3, p 593-607, June, 1983. 13 Fig, 11 Tab, 9 Ref.

Descriptors: *Energy, *Water resources development, *Mathematical models, *Resources development, Computer models, Water demand, Capacity, Optimization.

Development of new energy facilities can be constrained by the availability of raw energy and water resources as well as the location of major demand centers for these resources. A mathematical optimization model has been developed to help investigate alternatives for the capacity expansion of water-energy systems. The system consists of four subsystems: water, coal, electricity, and gas systems. Expressing new capacities, production, and distribution activities mathematically, the mathematical structure of the problem is defined and formulated as a multisystem, multiperiod capacity expansion problem. A major emphasis in development of this model was to handle very large scale systems. Benders decomposition is applied to the original problem to decompose it into three problems: capacity, production, and distribution problems. Each problem is solved by specialized algorithms. An example problem was solved. The computer code, CAPX1, for the capacity expansion of water-energy systems consists of approximately 7000 Fortran statements. The code is dimensioned to handle a water-energy system of 240 new projects, 50 existing facilities, 3 time periods, and for each subsystem, 400 nodes and 1000 arcs. (Moore-IVI)

LAND APPLICATIONS OF WASTEWATER: WATER RIGHTS ISSUES,
Western States Water Council, Salt Lake City, UT.
C. Bell, W. E. Cox, and G. Fiedler.
Journal of Water Resources Planning and Management, Vol. 109, No. 4, p 287-302, October, 1983. 25 Ref.

Descriptors: *Land disposal, *Water rights, *Wastewater disposal, Legal aspects, Water use, Return flow, Appropriation, Riparian rights, Municipal wastewater, Effluents.

Land application of municipal effluents is encouraged by existing federal water quality legislation and regulations as an alternative to conventional surface water discharge of partially treated effluent. However, conversion to the land application approach may impact downstream water users since the associated operations are likely to increase water consumption or change the location of return flows, or both. The legal status of such changes must be evaluated by application of state water law. In the western United States, the doctrine of prior appropriation protects appropriators whose water rights depend on return flows of prior appropriators by restricting changes in the manner in which the prior rights are exercised. In the East, the riparian doctrine sets limits on the amount of water consumption and place of water use. Although there is little direct precedent interpreting the principles of the two doctrines in relation to land application, potential constraints exist. This paper evaluates the significance of these constraints and the possible impact of water law on the adoption of the land application technique. (Author's abstract)

TRANSFERABLE DISCHARGE PERMIT TRADING UNDER VARYING STREAM CONDITIONS: A SIMULATION OF MULTIPERIOD PERMIT MARKET PERFORMANCE ON THE FOX RIVER, WISCONSIN,
Colby Coll., Waterville, ME. Dept. of Economics.
W. B. O'Neil.
Water Resources Research, Vol. 19, No. 3, p 608-612, June, 1983. 5 Tab, 4 Ref.

Descriptors: *Permits, *Water pollution control, Legislation, Model studies, Water quality, Cost analysis, Water temperature, Flow, Regulation, Wisconsin, Fox River.

The state of Wisconsin has recently established the legislative basis for what may be the first, operating water-pollution permit market in the United States. A multiperiod water quality planning model is developed to illustrate the performance of a TDP market under conditions of varying stream flow and temperature. The model is applied to the case of the Fox River and is used to compare the cost of achieving target water quality levels under conventional regulatory rules with the cost associated with operation of a TDP market. In addition to the cost estimates, the simulation of market performance yields information on the probable pattern of trading that may occur in the Fox River TDP market. The traditional rules for abatement allocation were about 40% more costly than the minimum-cost potential market solution. Under the worst case flow-temperature scenario the analysis showed that up to $7 million could be spent annu-

ally on the management of a market before the market would be a less-preferred strategy. The market could exhibit inefficiencies as a result of a lack of information or imperfect competition that would reduce the cost differential until a $6 million difference vanished. The empirical analysis of the Fox River provides strong support for further consideration of the permit market idea. (Moore-IVI)

WATER SUPPLY,
D. P. Sheer.
Civil Engineering, Vol. 53, No. 6, p 50-53, June, 1983. 2 Fig.

Descriptors: *Water supply management, *Water supply development, Water demand, Water supply, Washington, D.C., Virginia, Maryland, Design criteria, Water management.

Cooperative water supply agreements for the Washington, D.C. metropolitan area, based on state-of-the-art water resources management techniques, have ended a 30 year search for solutions to the region's recurring water shortages. Implementing these innovative operating procedures required eight separate agreements among agencys including the US Army Corps of Engineers, the states of Maryland and Virginia, the District of Columbia, two local utilities, and the Interstate Commission on the Potomac River Basin. The agreements are based primarily on almost costless, cooperative, improved operations of existing facilities, using state of the art flow and daily demand forecasting techniques. Construction of one small local reservoir, $30 million, is included, but that is not so much needed for the quantity of water it will hold as for the additional operational flexibility it provides. Overall system yield has been increased by nearly 50% and individual project yields by as much as 200%. Engineering achievements in the system include: the combination of optimization and simulation techniques to provide practical rules for operation of the entire system: the first large scale implementation of the National Weather Service River Forecast System, the development and implementation of a technique to predict water demand and the application of that technique in water source system design and operation; the combination of distribution analysis and hydrologic modeling to develop operating procedures for a complex water distribution system; the use of risk analysis to identify the start of potential droughts and to quantify the risks of continued drought: and the use of drought games to test and improve the water supply operating procedures and to illustrate the use of those procedures to decision makers, and the use of a small local reservoir to augment the yield of upstream impoundments. 6G. Ecologic Impact Of Water Development

DISTRIBUTION OF LARVAL FISHES RELATED TO POTENTIAL NAVIGATION IMPACTS ON THE UPPER MISSISSIPPI RIVER, POOL 7,
National Fishery Research Lab., La Crosse, WI.
L. E. Holland, and J. R. Sylvester.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 293-301, March, 1983. 5 Fig, 2 Tab, 13 Ref.

Descriptors: *Navigation, *Environmental effects, *Mississippi Rivers, *Fish, Larvae, Plankton, Diel distribution, Spatial distribution, Seasonal variation, Bass, Perch, Crappie, Drum, Shad, Carp, Channels, Boats.

Ichthyoplankton samples were collected twice monthly during spring and summer 1981 from a variety of habitats in Navigation Pool 7 of the upper Mississippi River. Larval-fish distributions in the pool and variations in those distributions were analyzed relative to potential impacts of increased commercial navigation. Although as many as 66 species of adults have been found in the area (33 considered common), only 17 taxa were identified from the collections. In April and May, most larvae were collected in main-channel and main-channel-border areas next to major expanses of shallow backwaters. White bass Morone chrysops, yellow perch Perca flavescens, and crappies Pomoxis spp. were predominant. Numerous catostomids also were taken. In June and July, most larvae were taken in the lower pool. Freshwater drum Aplodinotus grunniens and gizzard shad Dorosoma cepedianum predominated in these samples, which also included many cyprinids and centrarchids. Diel patterns of abundance varied with species and sampling location. Freshwater drums were more abundant near the surface at midnight than during the day. Common carp Cyprinus carpio were most abundant in collections at dusk, whereas all other cyprinids were most abundant at dusk and dawn. Numbers of gizzard shad also increased slightly at dusk. Total numbers of larvae collected were greatest at dusk in main-channel and main-channel-border samples; backwater areas produced the greatest catches at midnight and dawn. Seasonal, spatial, diel, and species-specific variations in larval fish abundances significantly influenced the proportion of the community potentially vulnerable to increased boat traffic through Pool 7. Descriptors: *Fish, *Habitats, *Behavior, *Distribution, Vegetation, Etheostoma, Meramec River, Missouri, Percidae, Substrates.

The distribution of three species of darters (Percidae) was studied with respect to vegetation and substrate preferences. The three species were greenside darter, Missouri saddled darter, and banded darter. The study was made in the Meramec River drainage, Missouri. Based on pooled field data from five collecting sites, Etheostoma blennioides and E. zonale showed a highly significant distribution with respect to vegetation. E. tetrazonum, in contrast, was associated with substrate and Etheostoma blennioides and E. zonale demonstrated a significant preference for vegetation in olfactory gradient choice chamber experiments. In preference tests in the artificial stream, E. blennioides and E. zonale showed preference for natural vegetation versus substrate. In trials where the fish were presented with alternating patches of natural and artificial vegetation, post hoc comparisons revealed a significant preference for natural vegetation over artificial vegetation and substrate. Silent Valley is a small and until recently unk
strip of dense forest in Kerala state, at the s
ernmost tip of India. The valley occupies 89
of what may be loosely described as tropical
forest. It lies on a plateau perched on the we
ghats, a range of mountains which border
1000 mile long coast of peninsular India. The
has an average annual rainfall of 4600 mm o
catchment of 77 sp km and the Kunthi is exp
to yield an annual run-off of 293,000,000 cu m.
river offers a straight head of 857 m, the high
Kerala. Silent Valley project envisages the
struction of a rolled concrete arch dam, 131 m
and 430 m long; the creation of a reservoir
merging 830 ha and impounding 317,000,000
of water; a water conductor system comprisi
4267 m long power tunnel, 260 m long pre
pipeline and a 2355 m long penstock branc
into two near the powerhouse; and a power st
on a small stream joining the Kunthi at the fo
the hills, 8 km from Mannarghat. Environme
ists are urging that the project be abandoned
the area declared a Biosphere Reserve. It is th
vestige of a natural climax vegetation of
region, and species in Silent Valley may
tremendous commercial potential. If the sche
abandoned the benefits that will not be rea
include: generation of 538 GWh of energy a
expected to yield $10 million from sales of p
and an increase in the GDP of $60-$100 mi
annually; irrigation of 10,000 ha in Palghat
Malappuram districts from the tailwaters; an
development of the most backward region o
state - the northern region of Malabar, where
project is to be situated. (Baker-IVI)

DEGRADATION OF THE RIVER NILE,
Research Inst. of Saad El Aali Side Effects, Cairo (Egypt).
S. Shalash.
International Water Power and Dam Construction, Vol. 35, No. 7, p 37-43, July, 1983. 7 Fig, 11 Tab.

Descriptors: *Environmental effects, *Water resources development, *Dam construction, Egypt, High Aswan Dam, Nile River, River beds, Sedimentation, Reservoirs.

One of the major tasks of the Research Institute of Saad El Aali Side Effects is to monitor the annual effects of degradation on the Nile River channel, particularly downstream of the existing hydraulic structures, occurring as a result of the construction of the High Aswan Dam in Egypt. The reach of the river currently under study starts from downstream of the low Aswan dam and ends upstream of the Delta barrage, a length of 953 km. There are five main control structures, each of which was built to a hydraulic design which did not affect the hydrological regime of the river before the construction of the High Aswan dam. Main hydrological parameters were recorded during the collecting of field data: suspended load measurements; water level records; discharge measurements and hydrographic survies. Downstream of Low Aswan, the drop in water levels varies between 42 and 40 cm for discharges of 10,000,000 cu m/day and 25,000,000 cu m/day, respectively. This is the total drop in water during the period 1964-1982. Downstream of Esna barrage the total drop in water level varies between 72 cm and 15 cm for discharges of 100,000,000 cu m/day and 200,000,000 cu m/day. For discharges of 80,000,000 cu m/day the drop in water levels was 76 cm for discharges of 80,000,000 cu m/day during the same period. Downstream of Naga Hammadi barrage the total drop in water levels is between 65 cm and 99 cm for discharges of 200,000,000 cu m/day and 800,000,000 cu m/day during the same period. Downstream of Asiut barrage the total drop in water levels are recorded as 49 cm and 78 cm for discharges of 150,000,000 cu m/day and 80,000,000 cu m/day during the same period. (Baker-IVI)

MALAYSIA ABANDONS TEMBELING,
Malaya Univ., Kuala Lumpur (Malaysia). Dept. of Geography.
S. S. Rachagan.
International Water Power and Dam Construction, Vol. 35, No. 7, p 43-47, July, 1983. 3 Fig, 6 Ref.

Descriptors: *Dam construction, *Environmental effects, *Water resources development, Planning, Reservoirs, Tembeling, Powerplants, Malaysia, Taman Negara, Public opinion.

A proposal to build a dam in Taman Negara for the Tembeling hydroelectric project was first brought forward in October 1971. The Sungai Tembeling is an upper tributary of Peninsula Malaysia's longest river, the Sungai Pahang. The need for flood mitigation and the hydroelectric power potential of the basin were the principal considerations for the dam. The project would have consisted of a main dam, saddle dams and associated works, including an intake feeding through a power tunnel to a conventional surface power station. With a total installed capacity of 110 MW comprising four units of 27.5 MW each, the average annual output of energy would be 441 GWh. A gated shaft spillway was planned with a capacity of 4800 cu m/sec for regulating flood discharges. Ecologists argued that flooding of such a large area could not be undertaken without societal consensus as to whether a large dam in this specific area was needed and sound as part of the nation's energy scheme. The key issue was that this area which had been proposed for the development of the dam and support structures was located in Malaysia's first and largest national park, a matter of great importance to the public. After 12 years of talking, researching, and considering alternatives, it appears that the environmentalists have convinced the Malaysian government of the need to abandon the proposed project. DEGRADATION OF THE RIVER NILE,
Research Inst. of Saad El Aali Side Effects, Cairo (Egypt).
S. Shalash.
International Water Power and Dam Construction, Vol. 35, No. 8, p 56-58, August, 1983. 7 Fig, 2 Tab.

Descriptors: *Environmental effects, *Dam construction, *Water resources development, Dams, Nile River, Egypt, High Aswan Dam, Deltas, Water levels, Discharges.

In order to monitor in the future the annual rate of change in the surface water slope of the Nile, the following methods were adopted to ensure good basic data for comparison. Water level gauges were selected at the beginning and end of reaches affected by degradation downstream of the hydraulic structures. Mean annual discharges downstream of each barrage, and water levels for the period 1963-1982 were measured. A relationship between the mean discharges and mean slopes for each reach are shown for the period 1963-1980. To calculate the slopes which correspond to the discharges before construction of the Aswan High dam, the same method was used. From the change in surface water slopes during the period 1963-1982, the maximum drop downstream of each structure was as follows: Low Aswan dam = 89 cm; Esna barrage = 65 cm; N. Hammadi barrage = 104 cm; and Asiut barrage = 96 cm. Eighteen years have elapsed since the High Aswan dam began to have an effect on the hydrological regime of the river Nile. The findings suggest a large difference between some of the theoretical forecasting and the actual results as regards the rate, maximum magnitude and time taken for the complete degradation process. THE JONGLEI CANAL: A DITCH TOO BIG,
R. Eshman.
Environment, Vol. 25, No. 5, p 15-20, June, 1983. 4 Fig, 40 Ref.

Descriptors: *Water resources development *Environmental effects, *Canals, Jonglei Canal, Egypt, Sudan, Nile, Drainage, Swamps, Hydrology.

The Jonglei Canal will run from Bor to Malakal in the southeastern district of Jonglei, Sudan when completed. It is not known how diverting water from the swamp ecosystem will affect the land, the indigenous people, and the hundreds of species of exotic wildlife in the Sudd. The purpose of the canal is to allow Egypt and Sudan to place 400,000 acres under irrigated cultivation and 4 million more when the canal is enlarged as planned. A total of 4.7 billion cu m of water will be diverted each year from the Sudd to irrigation projects downstream. The canal will also provide a time-saving transportation route from north to south. To achieve these ends no more than 19% of the Sudd will be drained. Critics of the canal foresee a possible breakdown in swamp ecology leading to up to 100% loss of these vital lands. A mathematical study has been made of the Nile hydrology. The Sudd's water table is replenished through the adsorption of water overspilling the river banks of the Nile in flood season. Reducing the amount of this overspill, which the Jonglei certainly would do, would affect the water table, possibly lowering it to such a degree as to affect the lives and environment of people far removed from the actual canal. A model was completed which assesses the amounts of inflow, outflow, seepage, and evaporation in the Nile region. (Baker-IVI)

SCHISTOSOMIASIS AND WATER PROJECTS: BREAKING THE LINK,
J. B. Tucker.

Environment, Vol. 25, No. 7, p 17-20, September, 1983. 2 Fig, 15 Ref.

Descriptors: *Human diseases, *Parasites, *Water resources development, *Environmental effects, *Schistosomiasis, Pathology, Diseases, Public health, Irrigation, Vectors, Drainage, Water management.

Schistosomiasis, after malaria, is now the world's most widespread, serious infectious disease. Many water resource development projects in tropical areas have had the unintended consequence of markedly increasing the prevalence of schistosomiasis in the local population. Water contact is the most critical variable in the transmission of schistosomiasis. Irrigation of formerly arid regions creates additional habitats for the snail vectors beyond those already present in ponds in rivers. Defects in the design or engineering of water projects may also provide new habitats for the snail hosts. The water projects have provided new opportunities for villagers to come into contact with the infested water, particularly when the projects are located close to villages in which no alternative water sources are available. The advent of perennial irrigation, in which the irrigation canals are is use year-round, has facilitated the multiplication of the snail vectors of schistosomiasis. Perennial irrigation has removed natural checks on the snail population enabling them to multiply out of control. Once snails have been introduced into an irrigation system it is impossible to eradicate them completely. If irrigation projects are supplied with efficient drainage, good water management and regular maintenance, it is possible to avoid an increase in the incidence of schistosomiasis. (Baker-IVI)

COMPARISON OF TWO ICHTHYOPLANKTON SAMPLING GEARS WITH NOTES ON MICRODISTRIBUTION OF FISH LARVAE IN A LARGE RIVER,
Academy of Natural Sciences of Philadelphia, Benedict, MD. Benedict Estuarine Research Lab.
R. P. Gallagher, and J. V. Conner.
Transactions of the American Fisheries Society, Vol. 112, No. 2B, p 280-285, March, 1983. 1 Fig, 5 Tab, 19 Ref.

Descriptors: *Fish, *Plankton, *Sampling, Biological samples, Larvae, Shad, Drum, Spatial distribution, Mississippi River.

A pilot comparison of two ichthyoplankton sampling gears was conducted in the lower Mississippi River, Louisiana. The two gears were (1) a 1-m-diameter conical plankton net towed at the surface and (2) two 0.5-m-diameter, bridleless, conical nets pushed at the surface from either side of the bow of a boat. Sampling was conducted on two different days, during light and dark periods, at three stations representing swift surface currents, sluggish currents, and slack water. Ichthyoplankton were more abundant in townet collections at the fastwater station during daylight hours and at the slackwater station at night, whereas pushed nets were more effective at the slackwater station during daylight hours and at the fastwater station at night. Shads Dorosoma spp. and freshwater drum Aplodinotus grunniens accounted for 94% of all fish larvae collected. Relative abundance of shads was greatest in daylight pushnet collections whereas drum were most abundant in daylight townet collections. Major additional trends: (1) shads, particularly protolarvae, were concentrated in the upper 50 cm of the water column in daylight collections, but were more uniformly distributed at night; (2) freshwater drums were more abundant in the 50-100-cm stratum during daylight collections, but were more uniformly distributed at night; (3) older freshwater drum larvae were more abundant in nighttime collections, whereas protolarvae were more abundant in daylight samples. A SIMPLE TOXICITY APPARATUS FOR CONTINUOUS FLOW WITH SMALL VOLUMES: DEMONSTRATION WITH MYSIDS AND NAPHTHALENE,
Lehigh Univ., Bethlehem, PA. Dept. of Biology.
R. L. Smith, and B. R. Hargreaves.
Bulletin of Environmental Contamination and Toxicology, Vol. 30, No. 1, p 406-412, April, 1983. 2 Fig, 20 Ref.

Descriptors: *Continuous flow, *Toxicity, *Invertebrates, Measuring instruments, Naphthalene, Mysids, Crustaceans.

To determine the toxicity of naphthalene to the mysid crustacean Neomysis americana, a small continuous flow toxicant exposure system using design features of Mariotte bottle chemostats was built. The Mariotte bottles were modified by the addition of air inlet restrictors, providing a stable flow at low pressure heads. Solutions of naphthalene in artificial seawater were prepared with 0.5% naphthalene in 80% ethanol and placed in one-liter bottles. Rate of naphthalene loss from the reservoirs was determined by continuously measuring naphthalene concentration from a reservoir for 77 hr. Flow remained constant within 1.3% for 53 hrs regardless of volume remaining in the reservoir. There was a slight tendency for newly introduced water to stratify at the bottom of the chamber. Naphthalene disappearance probably resulted from evaporation into the reservoir head space, which could be reduced in the future by passing intake air through a bottle containing naphthalene test solution before introducing it into the reservoir. Estimated continuous-flow 96 LC50s were 1280 micrograms/liter at 15 C and 850 micrograms/liter at 25 C. Naphthalene-induced mortality was significantly greater at 25 C than at 15 C for both concentrations. Low flow allowed use of artificial seawater in small amounts, making it possible to perform tests at an inland location with standard dilution water. (Baker-IVI)

DATA AUTOMATION FOR WATER SUPPLY MANAGEMENT,
Idaho Dept. of Water Resources, Boise.
R. J. Sutter, R. D. Carlson, and D. Lute.
Journal of Water Resources Planning and Management, Vol. 109, No. 3, p 237-252, July, 1983. 6 Fig, 7 Tab.

Descriptors: *Automation, *Water management, *Computers, *Reservoir management, Data acquisition, Data transmission, Data processing, Streamflow, Water storage, Water allocation, Water rights, Water conservation, Snake River, Idaho.

The available daily water supply of multi-reservoir river system, the Upper Snake River in Idaho, is managed more efficiently using an automated system of data collection, transmission, and processing. Streamflow, reservoir, and canal data are transmitted daily from remote gage sites and regional terminals to a central computer where a FORTRAN program computes natural (unregulated) flow and accounts for storage water supplies. Natural flow is distributed among various uses (primarily irrigation) and users based on established water rights. Storage allocations are monitored daily to better manage remaining supplies. Daily uses and resulting supplies are projected ahead by as much as one week to reduce river operation response times. The improved management correctly accounts for water distribution by rights and for storage allocations while promoting conservation of water supplies. (Author's abstract)

EXPERIMENTS TO ASSESS THE HYDRAU EFFICIENCY OF WELL SCREENS,
Water Research Centre, Marlow (England).
L. Clark, and P. A. Turner.
Ground Water, Vol. 21, No. 3, p 270-281, June, 1983. 13 Fig, 6 Tab, 15 Ref.

Descriptors: *Well screens, *Hydraulic prope Head loss, Hydraulic efficiency, Gravel aqu Intake velocity.

The hydraulic properties of commercial screens were investigated to determine w screen design features affected head loss. The program began with laboratory experiments continued as a field-scale experiment with th stallation of a well field in the Thames V Gravel Aquifer. The laboratory experiments cated that, for all practical purposes, the head attributable to all of the screens tested was ne ble. The experimental head loss, however, did from screen to screen, particularly at high i velocities, and the screens could be ranked o basis of their hydraulic efficiencies. This effici hierarchy is explained tentatively in terms o screen construction methods and slot geom The field experiments showed that the hydr performance of all well screens is independe

n design provided that the open area of the n is above about 10%. The field experiments indicated that the development capacity of a n in a gravel aquifer is not wholly dependent reen design, but that progressive development increase the hydraulic efficiency of a well. hor's abstract)

TRUCTING THE DRAKENSBERG PRES-TUNNELS,
de Witt.
ational Water Power and Dam Construction, 5, No. 6, p 13-22, June, 1983. 14 Fig, 1 Tab,

ptors: *Tunnel construction, *Reinforced ete, Construction, Tunnels, Concrete, Dra-rg, Pumped storage, Storage, Water supply pment.

ower conduits for the Drakensberg pumped e scheme traverse the Drakensberg escarp-ver a distance of some 5 km with an eleva-eparation of 570 m. The interbedded sand-siltstones and mudstones, comprising the and lower Beaufort series rocks of the o system in which the scheme has been con-d, exhibit very low primary and secondary abilities. Therefore, watertight linings were equired and unreinforced concrete linings provided over much of the length of the low re conduits. Considerations related to hydro-fracture of rocks, however, required a reappraisal of this approach in the high pressure waterways. Areal jacking, or uplift of the rock strata due to excess water pressure in zones of relatively low overburden stress, could not be tolerated, and the high pressure conduits through these areas were therefore provided with watertight steel linings. The final locations of the ends of the steel linings and the design of the associated cutoff arrangements were influenced by the proximity of faults. The design of the pressure tunnel linings in areas of adequate overburden stress was dictated by considerations of the durability of the rock traversed, the severe transient pressure fluctuations expected and hydro-fracture effects in the destressed rock close to the lining. The anticipated mechanism of hydro-fracture and erosion dictated the design of the lower pressure shaft and pressure tunnel linings. Use of prestressed concrete linings, prestressed by interface grouting, ensured prevention of hydro-fracture and erosion in the pressure tunnels and lower pressure shafts by providing a watertight lining which would ensure no hydraulic connection between the rock and the waterway, and by restressing the rock, forming a composite structure and full confinement of the rock. (Baker-IVI)

STEEL LININGS FOR HYDRO TUNNELS,
S. Jacobsen.
International Water Power and Dam Construction, Vol. 35, No. 6, p 23-25, April, 1983. 5 Fig, 1 Tab, 5 Ref.

Descriptors: *Tunnel linings, *Water supply development, Steel, Linings, Tunnels, Tunnel construction, Water transport, Mathematical studies.

The design of a ring stiffened lining that has been recently built is discussed to demonstrate how hazardous the design of such linings can be. In the steel linings considered, the original designer used specific Amstutz formulae. While it used to be the practice to carry out prestressing of steel linings by pressure grouting in old tunnels to prevent the water from infiltrating the lining and to increase the theoretical critical external pressure, this method is unreliable. The designer therefore assumed there would be a gap between the liner and the concrete originating from the inflating effect of the internal pressure during normal operation and the inability of rock and concrete to close the gap when the tunnel is being emptied or when the internal pressure is decreased. Since the distances from the neutral axis to the extreme outside and inside elements are so different, the maximum outside and inside stresses will also be different and it may be economical to use two grades of steel. In order to prevent buckling of the shell between the ring stiffeners, the stability of the shell must always be checked against the calculation of the critical external pressure for the ring system. Since the damage of the shell is less disastrous than the buckling of the rings, it may be reasonable to use lower safety factors for the shell than for the ring stiffeners. In designing the welds connecting the stiffener rings to the pipe shell the shear force is important. It is also advisable to calculate the stresses in the welding seam between ring and shell using the moment of inertia of the ring section and the total cross sectional area of the ring (including liner); to check the combined stress at the outer side of the shell at specified points; and to calculate the hoop stresses in the lining according to a particular method. THREE-DIMENSIONAL FINITE ELEMENT ANALYSIS OF THE LAPARAN DAM,
Bureau d'Ingenieurs-Conseils, Paris (France).
M. Hamon, P. Pouyet, and A. Carrere.
International Water Power and Dam Construction, Vol. 35, No. 8, p 19-24 and 29-30, August, 1983. 20 Fig, 15 Ref.

Descriptors: *Dam design, *Finite element method, Planning, Mathematical studies, Computers, France, Powerplants, Laparan Dam, Dams, Water resources development.

A comparison was made of the finite element analysis method specifically conceived for arch dams with the older trial load method, using the Laparan arch dam now being built in France. The thick-shell finite element analysis is a reliable and convenient tool for arch dam designers. At the design stage, in order to find the most efficient shapes for the structure, a relatively coarse mesh offers a satisfactory degree of accuracy in calculating stresses for quick and relatively cheap tests of the successive modifications made to the first conceptual design. At the subsequent stage of design justification, any desired degree of precision can easily be obtained, with a finer sub-division if necessary. If the designer wishes to explore in more detail the discontinuity where the dam meets the foundation and where the highest stresses usually occur, he can use the COBEF 3 program using block elements, with and without tensile stresses. It may be better to keep this type of analysis for special cases as, in a properly designed dam, the release of the tensile stresses that are almost inevitable at the heel, leads to an insignificant redistribution of the stresses in the dam and only slight changes in the existing compressive stresses. The programs COQEF 3 for thick shell analysis, and COBEF 3 with or without NOTEN 3 for no-tension conditions, can be considered as links in a chain of mutually compatible analyses for reliable and detailed exploration of an arch dam design. THIN ARCH DAM RESISTS ICE AND FLOODS,
Ministry of Water Conservancy and Power, Changchun (China).
W. Cai.
International Water Power and Dam Construction, Vol. 35, No. 8, p 37-39, August, 1983. 4 Fig.

Descriptors: *Arch dams, *Construction, Weathering, Floods, Ice, Dam construction, Water resources development.

Menkanshao power station on the Pushi River in the province of Lianoning consists of a thin arch dam, a tunnel, two penstocks, and a powerhouse. The catchment area is 198 sq km and the mean annual flow is 4.1 cu m/sec. The spillway design flood is estimated to be 1690 cu m/sec. The dam has withstood the sustained attacks of two floods larger than the spillway design flood and the extreme loading condition of ice thrust and freezing. The good performance of the dam is attributed to the reinforcement of the dam cylinder, particularly the heavier cantilever reinforcement. The principle of reinforcement is based on the assumption that stress in the arch direction is compression and the curved arch is flexible, while the cantilever, although free on the sliding joint, does experience moments in the lower part as a result of friction. Also moments may be produced because of uneven deformation and temperature variation. Since the cantilever is straight and shorter than the arch, it is stiller than the arch. Thus, considerable tension exists as indicated by computation. This is the reason why heavier reinforcement is placed in the cantilever direction. To improve performance in severe weather conditions, it is better to increase the cantilever reinforcement to about 0.1% of the cantilever section area, and the downstream face should be protected by an insulation layer. Also, it would be helpful to use electrical resistance wire buried in the sliding joint, to heat the joint and prevent it from freezing. (Baker-IVI)

EXISTING SCHEMES FOR CONSTRUCTING HIGH CONCRETE DAMS AND WAYS TO IMPROVE THEM,
V. I. Teleshev, and V. K. Loshak.
Hydrotechnical Construction, Vol. 16, No. 10, p 527-533, October, 1982. 3 Fig, 3 Tab, 7 Ref. Translated from Gidroteckhnicheskoe Stroitel'stvo, No. 10, p 6-11, October, 1982.

Descriptors: *Dam construction, *Concrete, Concrete dams, High dams, Design criteria, Construction, Hydroelectric plants, USSR.

To fulfill the indicated needs and accelerate construction of large hydrostations with concrete dams, at the current stage of development of hydrotechnical construction in the USSR it is necessary to increase the rate of placing concrete to 2 million cu m/yr with consideration of the fact that hydrostations are being constructed in narrow sites with a markedly confined field of operations. This requires the development and introduction of new concreting technologies, further improvement of concrete-placing operations, including preparation of the block for concreting and the preparation, transportation, and placement of the concrete mix with appropriate mechanization of all types of operations, including within the block. There are ways to improve each of the existing methods of delivering concrete to the block. The most promising of these are the craneless layer-by-layer, cableway, and crane trestleless (stepwise) methods. (Baker-IVI)

ADVANCED ENGINEERING IN THE DESIGN AND CONSTRUCTION OF THE CHIRKEY HYDROELECTRIC STATION,
M. A. Mironov, V. I. Grech, and N. I. Chalyi.
Hydrotechnical Construction, Vol. 17, No. 1, p 1-10, January, 1983. 6 Fig, 9 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 1, p 4-12, January, 1983.

Descriptors: *Construction, *Hydroelectric plants, Dam construction, Design criteria, Construction materials, Chirkey Hydroelectric Station, USSR.

The Chirkey hydrostation on the Sulak River in Dagestan ASSR is the most powerful hydrostation of the Sulak cascade and is intended to cover the peak-load part of the unified North Caucasian power system. The reservoir provided water for the development of irrigation agriculture on more than 300,000 ha, increased the water provision of water supply systems to a number of cities and towns, eliminated flooding of riparian lands in the lower reaches of the Sulak River and the need for annual reconstruction of protective embankments. A number of the engineering measures and technological methods successfully tested at Chirkey are presently being used elsewhere in the construction of large concrete dams and in the creation of turbine equipment for the powerful high-head turbines of the Nurek, Inguri, and Rogun hydrostations. In operation the Chirkey stations has an installed capacity of 1 million kW, possesses a 232.5 m high arch dam, and powerhouse with an original two-row arrangement of the units and has been proven to be a highly efficient structure. The developed and introduced layout design and industrial-technological measures made it possible to considerably reduce the amount of construction and installation works, to reduce the consumption of materials and cost of the structures, and to increase their reliability and operating qualities. The total saving from introducing just the main measures exceeded 20 million rubles. Among the most effective measures is the two-row layout of the units, the construction of a plug in the foundation of the arch dam with extension of the penstocks to the downstream face of the dam, the inclined intakes, and the new type of adjustable anchor support. The most important progressive industrial-technological measures are: the new technology of constructing concrete dams based on the use of cableways and a family of mechanisms for intrablock mechanization as the general concrete-placing and installing means; use of cantilevel type formwork of a new type; suspension technology of installing the embedded parts of the turbine; and excavation of rock cuts by the smooth splitting method. EXPERIENCE IN THE DESIGN AND CONSTRUCTION OF THE SPILLWAY PART OF THE ZEYA DAM,
V. N. Vagner, and Ya. P. Mirzaev.
Hydrotechnical Construction, Vol. 17, No. 1, p 10-18, January, 1983. 7 Fig, 1 Tab, 1 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 1, p 12-26, January, 1983.

Descriptors: *Construction, *Spillways, Design criteria, Dam construction, Concrete, Dams, Zeya Dam, USSR.

The buttress dam of the Zeya hydroelectric station with a crest length of 714 m, height of 116 m, upstream slope of 1:0.15 and downstream slope of 1:0.8 consists of bank abutments with a total length of 390 m, a powerhouse part with a length of 144 m, and a spillway part 180 m long. The dam buttresses within the bank abutments and spillway part have a thickness of 7 m and in the powerhouse part below the intake sill, 5 m. The recesses between the buttresses are, respectively 8 and 7 m. The recesses are covered by reinforced concrete slabs on the downstream face. According to laboratory studies the specimens of cavitation-resistant concrete M 400, MRZ 400 containing Portland cement M 400 and gravel of the fraction up to 40 mm with the addition of GKZh-94 placed in the spillway part of the Zeya dam showed stable results of strength, frost resistance, and cavitation resistance meeting the design requirements. The OVG-50 formworks for concreting the slab and RS-50 framework for the dividing wall used for constructing the spillway part of the dam provide the evenness and smoothness required by the design, are rather simple to handle, and are recommended for use. With the exception of the central part, construction of the monolithic spillway bucket is possible in the OVG-50 formwork. The central part of the bucket is concreted with the use of precast reinforced beams or panel formwork. The formation of the curvilinear surface of the spillway bucket from precast reinforced concrete beams permits simplifying concreting of the bucket with the obtainment of a good quality of the concrete surface, but further design developments are needed for reducing the cost and metal consumption of the works. PILE SELECTION AND DESIGN: LOCK AND DAM NO. 26 (REPLACEMENT),
B. H. Moore.
Transportation Research Record, Vol. 884, p 45-49, 1982. 8 Fig, 9 Ref.

Descriptors: *Piles, *Locks, *Dam design, Soil mechanics, Load distribution, Navigation, Decision making, Mississippi River, Illinois, Alton, Lock and Dam No. 26.

Lock and Dam No. 26 is a major navigation structure on the Mississippi River at Alton, Illinois. At the site there is a large, unbalanced horizontal water load of 24 ft. The soils at the site are sands, gravels, cobbles, boulders, and clay tills that are 80 ft. thick. The history of, and logic for, the selection of piling on this project is presented. The soil and foundation information available at each stage of design is outlined. The initial capacities were determined through experience and application of remote testing. The final choice of pile design was experience-based but supplemented by extensive explorations and on-site driving tests. At Lock and Dam No. 26, both testing and conservative design were used in developing the current plans. An evaluation of pile test extent and timing by using decision-analysis techniques is recommended. Until the driving and testing of production piles are complete, conservatism must govern design thinking. (Moore-IVI)

of interpolations in time, rather than the
idely used spatial interpolations, demon-
several benefits in the application of the
of characteristics to wave problems in
cs. Two such time-line schemes are pre-
nd analyzed in the solution of a linearized
mmer problem. Reachback time-line inter-
s, where the characteristic lines are pro-
ack before the current time step, demon-
strate less dampening than the correspondence spatial interpolation scheme at the same discretization. Implicit time-line interpolations, where the characteristic line is projected into the current time step, permit relaxation of the restrictive time step required by the Courant condition. An error analysis and numerical experiments demonstrate the degree of damping and dispersion introduced by both reachback and implicit time-line interpolation methods. The error analyses and their verification may encourage further application of these methods in appropriate problem domains. (Author's abstract)

INTERNAL FLOW IN HYDRAULIC JUMPS,
Windsor Univ. (Ontario). Dept. of Civil Engineering.
J. A. McCorquodale, and A. Khalifa.
Journal of Hydraulic Engineering, Vol. 109, No. 5, p 684-701, May, 1983. 11 Fig, 29 Ref.

Descriptors: *Hydraulic jump, *Stilling basins, *Internal flow, Mathematical models, Hydraulic models, Velocity, Shear, Centrifugal force, Turbulence pressure, Boundary layer, Entrained air.

Most stilling basins are designed on the basis of small scale model tests. The Froude Law is normally used for scaling the data; however, the relative effects of viscosity, entrained air, and entrance boundary layers are significantly different in the model and prototype. A mathematical model has been developed to help in the prediction of prototype performance from physical models. The technique used here is an extension of the strip integral method of R. Narayanan. The strip integral method uses velocity shape functions to permit the partial integration of the equations of motion. A Gaussian velocity distribution is used in the mixing zone and the power law is used in the inner layer. The mathematical model includes the bed shear, turbulent shear, the potential core, entrained air, centrifugal force and turbulence pressure. The model gives a fairly good prediction of the jump length, roller length, velocity distribution, water surface and pressure at the bed. The prediction of the growth of the boundary layer was not very good. The model indicated that the main effect of entrained air is the bulking of flow. The effects of centrifugal forces and turbulence pressures start to become significant for initial Froude numbers greater than 5. (Moore-IVI)

APPLICABILITY OF DAM-BREAK FLOOD WAVE MODELS,
Michigan Univ., Ann Arbor. Dept. of Civil Engineering.
N. D. Katopodes, and D. R. Schamber.
Journal of Hydraulic Engineering, Vol. 109, No. 5, p 702-721, May, 1983. 9 Fig, 18 Ref.

Descriptors: *Flood waves, *Flood routing, Mathematical models, Open channel flow, Kinematic waves, Dam failure, Flood depth.

Mathematical models based on the Saint-Venant equations for open channel flow often encounter serious difficulties when applied to natural channels. On the other hand, the approximate flood routing models used in practice may yield results which are in gross error. In this work five mathematical models are constructed based on equations ranging from the complete dynamic system to a simple normal-depth kinematic wave equation. The results of the models are compared between themselves and with experimental data, in the form of free-surface profiles and stage hydrographs. The models are then converted to dimensionless form, which reduces the number of independent parameters controlling their solution. The results of these calculations are presented in the form of dimensionless plots of maximum flood depth and time vs. distance along the channel, for various levels of truncation of the open-channel flow equations. Estimates for the permissible range of application of the simplified routing models are given, and recommendations are made for their judicious application. (Author's abstract)

TURBULENT UNDERFLOW IN A SHORT CHANNEL OF LIMITED DEPTH,
University of Western Ontario, London. Faculty of Engineering Science.
R. E. Baddour, and H. Abbink.
Journal of Hydraulic Engineering, Vol. 109, No. 5, p 722-740, May, 1983. 13 Fig, 19 Ref.

Descriptors: *Underflow, *Channel flow, *Turbulence, Density stratification, Internal jump, Flow instability, Hydraulic models, Mathematical models, Mixing, Froude number.

The flow characteristics of a turbulent underflow in a horizontal channel of limited depth are explored analytically and experimentally under a variety of upstream and downstream control conditions. Freshwater and salt water are used in the physical model to simulate a stable density stratification, and a contraction is adopted as a downstream control device. Three typical flow situations, respectively, distinguished as drowned internal jump, free internal jump, and flow instability, are observed depending on the nature of the interaction between the upstream and downstream controls. The hydraulic properties of each one of the flow situations are reviewed, and the experimental observations are compared with the results obtained from a hydraulic analysis. Maximum turbulent mixing is demonstrated to occur at a particular value of the discharge densimetric Froude number. Further increase of discharge densimetric Froude number is expected to result in a decrease in turbulent mixing and eventually to provoke a flow instability. (Author's abstract)

CALCULATION OF A LOCAL SCOUR DEPRESSION NEAR A PROTECTED CONCAVE BANK OF A GRAVEL-PEBBLE CHANNEL,
V. A. Bazilevich.
Hydrotechnical Construction, Vol. 16, No. 10, p 547-554, October, 1982. 2 Fig, 1 Tab, 14 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 19-20, October, 1982.

Descriptors: *Channel scour, *Mathematical studies, Gravel, Pebbles, Depression, Scour, Abrasion, Erosion, Meanders.

A simplified calculation method was developed on the basis of analyzing the results of calculations by the complete method of the Institute of Fluid Mechanics to predict the depth of a scour depression at the toe of a protected concave bank of a meander in gravel-pebble channels and to determine the rate of this scouring. The main conditions making it possible to use the simplified calculation method are; disregard of the balance of the bed load, and the nonuniformity of the flow in the scour depression at the protected concave bank of meanders. To perform the calculation it is necessary to have the value of the average slope of the free surface of the water on the axis of the flow, which is assumed constant during deformation of the bottom of the meander. In the calculation one determines the vertically averaged velocity of the nonuniform flow and the friction velocity in the scour depression, which must be compared with the friction velocity corresponding to the detachment of the erosion pavement of inhomogeneous soil composing the bottom of the meander. To check whether the calculated deepening of the bottom can occur during the duration of the calculated flood on the basis of the value of the bed-load discharge, the rate of deepening of the bottom in the scour depression is determined with the use of a method provided. The reliability of the recommended simplified calculation method is confirmed by the results of comparing the calculated and experimental values. (Baker-IVI)

PRESSURE FLUCTUATIONS ON THE BOTTOM OF OPEN-CHANNEL TURBULENT FLOWS IN SPILLWAY STRUCTURES,
A. A. Ivoilov.
Hydrotechnical Construction, Vol. 16, No. 10, p 554-559, October, 1982. 3 Fig, 1 Tab, 10 Ref.

Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 23-25, October, 1982.

Descriptors: *Spillways, *Turbulence, *Hydraulic engineering, Construction, Pressure, Design criteria, Dam construction, Aeration.

Correct consideration of the hydrodynamic effect of a turbulent flow on elements of spillway structures is one of the important problems of modern hydraulic engineering. One characteristic of open-channel flows on high-head spillway structures is their severe aeration within the conveyance channel, and when the flow is ejected from the structure by means of a ski-jump bucket its considerable fragmentation during free fall is also noted. A theoretical analysis of the equations of hydrodynamics describing the motion of a water-air mixture shows that in this case, compared to the flow of a one-phase fluid, a number of additional factors have an effect, which can change the hydrodynamic characteristics of the flow. Pressure fluctuations on the bottom of the gradually varied and markedly nonuniform flow are reproduced sufficiently well on models of the structures, and the slight distortions of the energy-frequency spectrum caused by the nonmodelability of aeration and microturbulence of the flow can be disregarded. If it is necessary to conduct dynamic calculations of the structures, when a rigorous and spectrum-differentiated consideration of the pressure fluctuations is required, corrections obtained on the basis of the examined investigations can be introduced. The intensity of the pressure fluctuations on the bottom of the flow under the free-falling flow under prototype conditions compared to the model data noticeably decreases due to aeration and fragmentation of the flow, which for all practical purposes are not reproduced in the model. ON-SITE INVESTIGATIONS OF THE HYDRAULIC REGIMES OF A TRANSITION STRUCTURE,
P. V. Kutsenko, O. V. Kikish, and T. N. Rogovoi.
Hydrotechnical Construction, Vol. 16, No. 11, p 613-616, November, 1982. 1 Fig, 1 Tab, 7 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 11, p 27-29, November, 1982.

Descriptors: *Channels, *Powerplants, *Water levels, Hydraulic machinery, Construction, Design criteria.

The design and operation of transition structures on channels of thermal and nuclear power stations should provide reliable, accident free operation of these structures. To maintain the necessary water levels and to join the pools a transition structure made in the manner of a tower spillway was constructed on the discharge channel at the Zaporozh'e state regional electric power station. The transition structure represents two unregulated spillways in the form of an overflow reinforced-concrete wall with heights of 2.46 and 2.6 m, thickness of 0.6 m, and total length of the spillway face of 75 m. Investigations of the hydraulic operating regimes of the transition structure were carried out in the fall of 1979 and the spring of 1980. During the first stage the investigations were conducted at various discharges of water through the structure into the lower pool and at a water level in the lower pool of the structure of 18.00 m. During the second stage the investigations of the hydraulic operating regimes of the transition structure were carried out at a constant discharge of 103 cu m/sec through it and with the water level in the lower pool of the structure raised to 18.55 m. A vacuum is created in the initial section of the discharge pipes of the transition structure, which explains the entrapment of air with water in them. Air accumulates in the pipes owing to the Archimedean buoyant force directed opposite to the flow of the water. It is possible to provide discharges under acceptable conditions if a vacuum is absent at the inlet section of the pressure pipes. (Baker-IVI)
W84-01744

HYDRAULIC INVESTIGATIONS OF FLOOD PASSAGE OVER A FLOODPLAIN AROUND CHANNEL STRUCTURES,
D. V. Shterenlikht, and I. F. Pikalova.
Hydrotechnical Construction, Vol. 16, No. 11, p 616-622, November, 1982. 4 Fig, 10 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 11, p 29-32. November, 1982.

Descriptors: *Flood plains, *Channels, *Erosion, Hydraulics, Mathematical studies, Flood profiles, Construction, Design criteria.

Analytical and experimental investigations were conducted the movement of the flow over the floodplain around various types of channel structures. The experimental part of the work involved two flumes measuring 3.0 x 23.0 and 1.0 x 19.0 m in plan. The models were made of sand with concrete-crust coating and represented half of a parabolic channel with a rectangular floodplain adjacent to it. The experiments were conducted with three different values of the width of the floodplain and three values of its roughness coefficient. The floodplain did not have a transverse slope; the longitudinal slope of the floodplain and channel was 0.0012. Investigations of channel structures around which the flow passed were carried out at water discharges of low probability, when a single through-going flow is formed on the flood-plain and nonparallelism of the maximum velocity threads of the channel and floodplain flows is the least probable. The performance of nonoverflow guide groins on the floodplain was studied to create the most favorable conditions of streaming of the flow around the channel structures. Groins of an elliptical configuration shifted downstream relative to the site showed the best performance. Such an arrangement of the groins promoted a decrease of nonuniformity of the velocity distribution at the site of the structure and a decrease of maximum velocities in the immediate vicinity of the structure. HYDRAULIC LOADS ON THE SOLID BOUNDARY OF A FLOW UNDER THE EFFECT OF A FRAGMENTED JET,
L. D. Lentyaev, L. V. Smirnov, and A. G. Shubin.
Hydrotechnical Construction, Vol. 17, No. 1, p 28-31, January, 1983. 5 Fig, 6 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 1, p 22-24, January, 1983.

Descriptors: *Fluid mechanics, *Jets, Nozzles, Fragmented jet, Hydraulic loading, Energy.

One of the main advantages of the scheme of joining pools by deflecting the jet compared to the scheme of dissipating the energy of the flow in a hydraulic jump is the substantially smaller level of dynamic loads on revetment elements of the lower pool due to fragmentation of the flow in the bay. Earlier recommendations concerning the structure of loading a solid boundary of a flow by fragmented falling jets of water when joining pools with deflection of the jet are confirmed by direct measurements of the dynamic reactions and can be recommended to hydraulic engineers for use in design practice when calculating revetment elements of lower pools of hydraulic structures. A schematic diagram of the experiments performed is provided. The jet of water, formed by a nozzle having a 0.2 x 0.5 m rectangular section and 1:4 contraction coefficient, which was fastened on a pressure tank, was discharged into a 4-m side horizontal flume with vertical walls equipped with an end device regulating filling of the flume in limits from 0 to 1.5 m. The head above the center of the nozzle was 2.3 and 7.7 m, which corresponded to nozzle discharges of 0.670 and 1.225 cu m/sec. The vertical distance from the nozzle axis to the flume bottom was 7.9 m. A the sensor of the total load a small steel beam was used, rigidly fixed on one end and free on the other. The beam-sensor was installed under the center of fall of the jet, flush with the flume bottom. (Baker-IVI)

A rigorous formulation and an analytical solu
are presented to the problem of determining
optimum capacity of a run-of-river plant. Am
the evaluation criteria available, a maximizatio
the net benefit is generally considered as the
appropriate one. The net benefit is described as
difference between total benefits and total cost
is expressed in average annual terms. A ru
river plant may be viewed as a system w
converts a stochastic input process, streamfl
into a stochastic output process, power. The
proach does not suffer from usual shortcomi
but rather it shows that even an analytical solu
of the exact formulation exists. The resulting
pacity decision rule is simple to implement,
provides valuable guidance to judge the poss
effect of imprecise cost and benefit data on
design capacity. The objective function has
typical structure of the objective functions desc
ing single-period inventory decision probl
under risk. The distinguishing characteristic of
kind of problem is that there is only one opport
ty for procurement, scale or target decisions.
theory and results of this study may be applie
any hydro plant, with or without pondage, if
objective is maximum exploitation of energy
not the provision of peak capacity. (Baker-I

ystem and philosophy used to develop pump-turbine designs are reviewed. Design ves are to produce equipment which has the teristics of reliability, easy servicing, oper- flexibility and high performance. The suc- this approach is made possible by integrat- sign history and field experience into com- design and analysis systems. These systems latest analytical tools to provide a thorough tanding of hydraulic, mechanical and oper- behavior. They are supplemented by a ehensive set of statistics on existing units and operating problems. Extensive testing of and operating equipment provides further for design optimization and the feedback to make further improvements. Hydraulic improvements are pursued using a mean line performance prediction program to cal- culate both pump and turbine cycle performance as a function of wicket gate opening. Parametric studies of changes in water passage geometry are conducted and evaluated to maximize performance. Mechanical design refinements are studied using the finite element method. Two- and three-dimensional finite element method analyses are used to predict the static and dynamic structural response needed to achieve the desired reliability in the detailed mechanical design. An extensively correlated hydraulic transient program is used to evaluate and refine field behavior during the design process. Model test data, site water passageways, steady and dynamic loads and governor data are combined to predict machine behavior during start-up, load rejection, and operating mode change. Final refinements of operation are developed through comprehensive field tests during unit commissioning. (Baker-IVI)

MECHANICAL EQUIPMENT FOR DINORWIC.
International Water Power and Dam Construction, Vol. 35, No. 4, p 29-31, April, 1983. 3 Fig, 2 Tab.

Descriptors: *Mechanical equipment, *Fatigue, *Pumped storage, Dam construction, Storage, Turbines, Valves, Penstocks.

At the Dinorwic pumped storage station, equipment is designed to stabilize frequency variations; a machine may change from spinning to generation and back to spinning four or five times an hour. The design of the mechanical equipment such as pump turbines valves, and penstocks has been strongly influenced by the requirements to counter any problems of fatigue. A special program was developed for testing those components at risk, such as top and bottom covers of the pump-turbine spiral casings and elements of the main inlet valves. Components which were to be subjected to the fatigue inducing forces were examined ultrasonically, and the position and size of any imperfection were corrected. One unusual feature if the use of a Ringfeder locking assembly for the guidevane linkage. A simple arrangement of concentric tapered rings allows the guidevane link to slip at a predetermined torque higher than the normal operating value. Should material enter the water system and jam the guide vanes, the Ringfeder mechanism will prevent any of them from breaking loose from the assembly and causing damage to adjacent ones. Other components of the system that have unusual operating parameters are the main inlet valves which have to operate quickly and reliably, and if necessary, close without external power. (Baker-IVI)

OPTIMIZATION OF DREDGE AND VARIABLE DISPLACEMENT PUMPS,
P. R. Khlopenkov.
Hydrotechnical Construction, Vol. 16, No. 11, p 622-630, November, 1982. 6 Fig, 9 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 11, p 33-37, November, 1982.

Descriptors: *Pumps, *Mechanical equipment, *Water delivery, Operation wastes, Energy, Dredging, Centrifugal pumps.

Nonproductive expenditures of electric energy occur at pumping stations with variable operating regimes; with a decrease of water consumption the head increases, whereas the network resistance decreases. As a consequence, the head exceeds the required values by 10-40% for the greater part of the day. This leads not only to an overconsumption of energy but also worsens the operating conditions of the network. The optimal solution is regulation of the head and delivery by changing the dimensions of the main operating elements of the pump by gradual variation of the outlet diameter of the impeller, or gradual variation of the width of the passages in the impeller and discharge pipe, or simultaneously by changing in certain combinations both the outlet diameter of the impeller and width of the impeller passages and discharge pipe. Centrifugal pumps with an adjustable outlet diameter and width of the impeller passage and discharge pipe were shown to improve operation of a given network and made it possible to reduce energy expenditures at pumping stations by 10-20%. By obtaining clean water directly from sludge and directly in the pump without pressure losses, it was possible to solve the problem of protecting pump elements from abrasion by a wall boundary layer without increasing energy expenditures on injecting clean water into the internal cavity of the pump. By fractionation of sludge in pressure settling tanks, without pressure losses, it was possible to use inferior borrow pits near hydrotechnical construction sites for reducing transportation expenditures on delivering inert materials to the site. IMPROVEMENT OF THE MECHANICAL EQUIPMENT OF HIGH-HEAD SPILLWAYS,
M. F. Krasil'nikov.
Hydrotechnical Construction, Vol. 16, No. 12, p 644-652, December, 1982. 8 Fig, 4 Tab, 6 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 12, p 38-43, December, 1982.

Descriptors: *Spillways, *Mechanical equipment, *Gates, Construction, High pressure gates.

The problem of creating high-pressure gates for high-head powerstations has become acute in connection with expansion of the construction of hydrostations combining high heads with large waste discharges. Studies have been made in three principal directions to solve the problem: creation of reliable and effective designs of the main regulating and emergency guard gates for heads up to 200 m with an area of the opening being covered up to 60 sq m; creation of reliable and effective large-capacity lifting gear and with a large height of lifting the gates, supporting parts for large loads, and designs of gate seals with the use of new materials; the search for new layout designs of the surplusing works which effectively dissipate the excess kinetic energy of the high velocity flow beyond the main regulating gate to eliminate the destructive action of the flow on the structural part of the structure. The studies have demonstrated the real possibility and economic expediency of manufacturing mechanical equipment for regulating large waste discharges at a head of 200 m, and the effectiveness of using the effect of swirling of the discharging flow in spillway systems. Further perfection of the mechanical equipment of high-head spillways should improve the layouts, increase the precision and quality of manufacturing gates and drives, operating reliability of the seals, vibration resistance, and protection from cavitation. EVALUATION OF STRESSES IN ELEMENTS OF THE LOCK GATES ON THE MOSCOW CANAL,
V. G. Abrosimov, O. L. Bandin, A. P. Gusenkov, and V. P. Kogaev.
Hydrotechnical Construction, Vol. 16, No. 2, p 653-656, December, 1982. 3 Fig, 2 Tab, 5 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 12, p 43-45, December, 1982.

Descriptors: *Lock gates, *Stress, *Evaluation, *Canals, Moscow Canal, USSR, Gates, Mechanical equipment, Mechanical failure.

Experience gained in operating the mechanical equipment of the Moscow Canal and certain other transporting hydraulic structures indicates that the reliable operation of engineering works is to a considerable degree determined by the strength of lock gates. The main elements of the gates include the load-bearing space truss consisting of riveted and welded elements, support elements, retaining elements and watertight skin plates. Atter several years of operation, cracks were found in the weld zone of the gates near the attachment holes in the retaining elements, in the angle flanges of the lower tie beam, and in the skin plate. On the basis of analyzing the working conditions of the elements of the lock gates and on-site strain measurements, the low cycle character of loading and

the possibility of failure in the maximally stressed zones was confirmed to be a consequence of the occurrence of repeated elastoplastic deformations in the structural material. It is necessary to calculate and determine experimentally the low-cycle life of elements of the load-bearing structures of lock gates and to work out recommendations on increasing their resistance to cyclic failure. 8D. Soil Mechanics

THE EXCAVATION OF LARGE UNDERGROUND OPENINGS: A NUMERICAL SIMULATION,
Istituto Sperimentale Modelli e Strutture SpA, Bergamo (Italy).
M. Borsetto, and A. Peano.
International Water Power and Dam Construction, Vol. 35, No. 6, p 28-33, June, 1983. 9 Fig, 1 Tab, 34 Ref.

Descriptors: *Excavations, *Model studies, *Mathematical models, Rock excavation, Powerplants, Rock mechanics, Rocks.

The relative merits of various mathematical models used in the computations for constructing eight underground stations owned by the Italian power authority are discussed. The first attempt to use finite element models was based on the assumption of elastic material behavior. In the case of Lake Delio power station the aim was to identify the original stress state by fitting extensometer readings made during the excavation of the opening. Discrepancies lead to the development of more refined mathematical models. Hence the material was assumed to be linearly elastic under compression only: tensile stresses were redistributed according to the iterative method developed by Zienkiewicz. A realistic material model of the rock mass calls for a Mohr-Coloumb failure criterion, a strain softening law and a tensile cut-off. This approach was implemented in the computer program NOLIPL based on the stress transfer technique. The availability of realistic material models makes it possible to interpret the deformational behavior of the rock mass at various excavation stages and therefore it provides an adequate check of the design assumptions. To monitor the deformation occurring in the rock mass various rock extensometers are usually installed. A good agreement between the observed and expected performance of the opening confirms the designer's safety assessment. Some important cost- and time-savings procedures include reducing the size of the discretization by the boundary elements technique or by modelling the boundary conditions using infinite-finite elements; minimizing the number of degrees of freedom by using accurate approximation techniques based on high order polynomials; and tuning the algorithm for the solution of the system of linear equations on the basis of the characteristics of the hardware system. Typical aspects include a reduction in the paging in virtual storage computers and optimization of vector operations. (Baker-IVI)

MATERIALS FOR HIGH EMBANKMENT DAMS,
Vsesoyuznyi Gidroproektno-Izyskatel'skii i Nauchno-Issledovatel'skii Inst. 'Gidroproekt', Moscow (USSR).
V. I. Vutsel, Yu. K. Zaretsky, E. I. Vorontsov, A. G. Chernilov, and B. D. Chumichev.
International Water Power and Dam Construction, Vol. 35, No. 8, p 33-37, August, 1983. 6 Fig, 4 Ref.

Descriptors: *Dam construction, *Construction materials, Embankments, Soil properties, Testing procedures, Tensile stress, Stress.

In designing embankment dams the following main calculations are necessary: determination of the seepage stability of the dam body, its foundations, the banks and slopes; calculation of the settlement of the dam body and foundation to determine the required freeboard and the value of differential settlement of its different elements; calculation of horizontal displacements of the dam elements. The analysis for high (over 70 m), rockfill dams, used to determine their rational designs, should incorporate a considerable range of variations of stresses acting in the dam body. The stress, strain and stability analyses of high rockfill dams should take into consideration the real non-linear stress-strain relations. Analyses of soil materials are performed with the help of computers using programs based on the deformation theory of plasticity or the theory of plastic flow, and taking into account the possible consolidation of the clayey soils in anti-seepage dam elements, and the technique, sequences and time schedule of the construction program. Initial soil placement parameters are usually determined by the standard compaction method, involving the tamping of soils with different moisture contents at the standard impact impulse and the compacting effort. Strength and deformability characteristics of materials for anti-seepage elements are determined using the triaxial apparatus for testing specimens 60 and 100 mm in diameter. For assignment of the soil density, the concept of the relative compaction is used. (Baker-IVI)

EVALUATION OF THE ACCURACY OF CALCULATING THE STABILITY OF SLOPES OF EARTH DAMS IN CHECK CALCULATIONS OF SLOPES THAT FAILED,
N. A. Krasil'nikov.
Hydrotechnical Construction, Vol. 16, No. 10, p 560-567, October, 1982. 6 Fig, 5 Tab, 21 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 26-30, October, 1982.

Descriptors: *Earth dams, *Stability, *Mathematical studies, Dam construction, Dams, Slopes, Hydraulics, Soil properties, Computers.

To select the optimal method of calculating the stability of slopes of earth dams and to evaluate its accuracy, check calculations of the stability of more than 50 slopes that failed were performed. The calculations were performed on a computer simultaneously by several of the most used methods of calculation realizing the hypothesis of a circular-arc surface of sliding. These calculation methods are sufficient for conditions of earth dams. At present it is advisable to use the VNIIG-Terzaghi and Bishop methods in practical calculations of earth dams. Bishop's method, realizing Krey's model does not have any real advantages over the VNIIG-Terzaghi method. One of the slopes failed as a consequence of imperfection or inaccuracy of the calculation method. All failures of real slopes of structures occurred owing to the underestimation of the engineering-geological conditions of the foundation, insufficient consideration of the process of consolidation of the clay soil, or unfounded overestimation of the parameters of the shear strength of the foundation soil at the design stage. Therefore, the principal source for increasing the reliability of predictions of the stability of the slopes of earth dams lies in the timely refinement of the initial information. It is advisable to practice more widely the construction and investigation of experimental embankments in the preconstruction period. During further elaboration of problems of calculating the stability of earth dams it is advisable to use the achievements of the moden theory of landslide processes, bearing in mind that an earth dam works under specific conditions which are rarely found in nature. Soil mechanics, Hydrodynamics, Stress release.

Long-term cut-slope stability is directly depende
of seepage force and, therefore, the ultima
groundwater level within the soils in the cut. T
design of clay slopes for long-term stability w
studied in relation to mode of failure, soil te
methods, method of analysis, selection of para
eters, and time dependency of stability. Long-ter
safety of overconsolidated clay slopes can be es
mated by using the drained friction angle (plus
low residual cohesion) and seepage forces based
a high water table, determined by modified Bish
or a similar analysis. Stress release in overconso
dated clays is a time-dependent function, and
estimate can be made from the assumption of th
simple hydrodynamic lag model and a depth
failure plane based on the geometry of the mo
critical section. (Moore-IVI)

Salal Dam, Water resources development, Leal
age.

The Salal Dam is located in the northern loop
the Chenab river. The structure will be one of th
highest rockfill structures in the country. It i
volves placement of 8,000,000 cu m of compacte
materials, 96,000 m of grouting, and forms a majo
constituent of the Salal hydro project. The area
the right abutment consists of highly jointed dolo
mite with a number of shear zones and chart band
The left abutment of the dam is guided by th
bedding planes of the highly jointed dolomite
which strike almost in a transverse direction to th
axis and dip at 55 degrees northwards. A 50 mm
thick gunite has been applied to the full core bas
and on the downstream rock face of the cor
trench. In the reaches within the core trenc
where the permeability of the bedrock did no
reduce to 10 Lugeons after consolidation groutin
a 6 m deep concrete cutoff has been provided wi
a 1 m base width and side slopes of 4 V to 1 H an
a longitudinal slope of 1 V to 2 H. Grout intake i
the shear zones is not excessive because of th
presence of clayey material. High permeabilit
values in the upper stages could be attributed t
leakage through the weathered rock and the oper

it of joints to the surface. A drainage system
een provided on the downstream side of the
base in view of the shear zones running
el to the river course and the difficulty in
g them with cement grout. (Baker-IVI)

criteria, Engineering, Construction, Dams,
dams, Japan.

of rolled concrete in dam construction has
er of advantages, some of which apply
arly to Japan where the river flows are
and the transport of fill material would
ransport resources. The use of rolled con-
lls for a difference approach to dam con-
n. There is a way of determining the dam
ross section suitable for construction on
y inferior and weak foundation ground of
often encountered. In contrast to the arch
ie use of rolled concrete may be said to
stresses and make use of relatively weak
. Rolled concrete is mainly placed in a
tal plane as opposed to normal concrete
is applied at one point and therefore the
n of an appropriate equipment system is
portant. The fundamental aim when using rolled concrete is to adopt the concept of the conventional concrete gravity dam through the design. Through practical application of rolled concrete in dam construction, many of the apparent problems have been solved. This method was suitable for current conditions in the construction of gravity dams. The ease of placment is greatly enhanced by the considerable reduction in contraction joints or construction joints, and work on the placement area is also carried out more safely. The method has been successfully applied to dams as well as to appurtenant structures. The most appropriate types of dam to make use of the rolled concrete method are likely to be those where the plan area of the dam body is wide in proportion to the height and where there are few structures inside the dam body. HYDROTECHNICAL CONCRETE OF THE UST-ILIM HYDROELECTRIC STATION,
M. A. Sadovich.
Hydrotechnical Construction, Vol. 16, No. 11, p 598-605, November, 1982. 1 Fig, 5 Tab, 13 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 11, p 19-23, November, 1982.

Descriptors: *Concrete, *Dam construction, Powerplants, Concrete construction, Concrete technology, Bratsk hydrostation, Ust-Ilim hydrostation.

The similarity of the climatic and engineering-geologic conditions of the construction of the Bratsk and Ust-Ilim hydroelectric stations and the participation of a common team of designers and builders in the construction led to a continuity of design, but considerable difference in hydrotechnical concrete used at both sites. A decrease of cement contents compared to analogous compositions of the Bratsk hydrostation, improvement of concrete quality, and increase in general technological discipline attest to definite progress in the technology of hydrotechnical concrete used at the Ust-Ilim hydrostation. Further progress was noted with the selection of a rational technology on the basis of experience at the Bratsk and Ust-Ilim stations, modernization of individual components, and the creation of a system of automatic compensation of the variability of the moisture content of aggregates at concrete plants, mechanization of concreting operations in the blocks, and increases of general efficiency. Site tests of the concrete of the Ust-Ilim dam showed that the solid concrete mass was particularly impermeable and the relatively small seepage flow occurred along the cracks and horizontal joints. One of the directions of the rational use of concrete can be a further reduction of the cement contents in concrete of the upstream column to an extent which does not cause damage when used as a material and will promote an increase of crack resistance of individual blocks and structures as a whole. Analysis of test results indicated that it was necessary to take into account the conditions of hardening of the concrete in the structure when assigning the concrete composition. In massive and underwater structures, concretes with low cement contents harden most intensely and for the longest time. The strength reserves occurring in this case remain unused. In outer surface zones, conversely, early drying and other unfavorable factors can lead to a decrease of the potential possibilities of concrete. (Baker-IVI)

STRUCTURE AND FROST RESISTANCE OF SAND CONCRETES WITH CHEMICAL ADDITIVES,
L. B. Gol'denberg, S. L. Oganeyants, and G. F. Voevoda.
Hydrotechnical Construction, Vol. 16, No. 11, p 606-608, November, 1982. 1 Fig, 3 Tab, 3 Ref. Translated from Gidrotekhnickeskoe Stroitel'stvo, No. 11, p 23-25, November, 1982.

Descriptors: *Concrete technology, *Concrete additives, *Freezing, Frost, Concrete, Dam construction, Construction materials, Cold regions.

The introduction of chemical additives, changing the initial water content of the concrete mix and kinetics of the structural formation of concrete, have an effect on its porosity and, consequently, on frost resistance. The structure and frost resistance of sand concretes were studied after the addition of the additives superplasticizers S-3 and NIL-20, the set-accelerator sodium sulfate, and combined additives composed of them. The introduction of plasticizing and combined additives causing a decrease of the initial water content of the cement sand mixtures from 210 to 180-185 l/cu m and an increase of the unit weight of concrete from 2315 to 2350-2360 kg/cu m leads to a decrease of the total volume of pores of the concrete from 16.2 to 12.9-13.2%. The addition of sodium sulfate did not have a substantial effect on the porosity. A reduction of the volume of open capillary porosity should lead to an increase of the frost resistance of concrete, which was demonstrated in further testing to be the case. The coefficient of frost resistance after 300 freeze-thaw cycles for concretes without an additive or with only an accelerator is 0.92-0.94 and for concretes with plasticizing and combined additives 1.00-1.20. The results obtained on analyzing the relation between frost resistance of concrete and its structure are comparable to the results obtained on the basis of direct tests. The introduction of chemical plasticizing and combined additives S-3, NIL-20, S-3+SS, NIL-20+SS, causing a decrease of the initial water content, leads to modification of the structure of concrete, decreasing the volume of open capillary pores, and increases the frost resistance of concrete. ON-SITE OBSERVATION OF THE CONCRETE STRUCTURES OF THE KAKHOVKA HYDROELECTRIC STATION,
S. Ya. Eidel'man.
Hydrotechnical Construction, Vol. 16, No. 12, p 657-663, December, 1982. 5 Fig, 4 Tab, 7 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 12, p 46-49, December, 1982.

Descriptors: *Concrete, *Hydroelectric plants, Construction, Failure, Stress, Dam construction, Dams, Kakhovka Hydroelectric Station.

The first unit of the Kakhovka hydroelectric station, whose total capacity is 321 MW, was started up 25 years ago. Settlements of the concrete structures of the hydrostation, which are diminishing, have been drawn out over more than 20 years. An increment of the settlement in recent years on some structures has ceased. The exception is one section of the downstream dolphin of the navigation lock located on an insufficiently compacted sand foundation bed. The greater part (80-90%) of the seepage head on the dam is lost on the blanket part of the underground contour, including the natural blanket of liman-marine silts. On the upstream sheet-pile wall 10-12% of the head is lost. The piezometric levels vary almost as a linear function of the fluctuations of the lower pool level. The character of the diagram of contact stresses in the bed soil, which is governed by the sequence of concreting the dam and increase of the upper pool level during filling of the reservoir, remained stable during the subsequent years of operation. A slight increase of contact stresses was noted at certain points of the bed under the indent of the dam. The stresses in the reinforcement of the massive foundation slabs are small. In the vertical reinforcement of the retaining walls the thermal stresses of the construction period reduced the tension on the back side and increase compression on the face side. Tensile stresses up to 140 MPa were measured in the reinforcement of the spiral casing after filling it with water. String-type sensors were installed in the concrete structures without the use of vulcanization of the joints of the cables. This and also the shortcoming of the design of the sensors resulted in their gradual failure. However, about 150 sensors that remained sealed have been operating for more than 25 years in the

concrete and saturated bed sands, and their readings are reliable. (Baker-IVI)

International Water Power and Dam Construction, Vol. 35, No. 3, p 33-35, March, 1983. 5 Fig, 3 Tab.

Descriptors: *Steel, *Construction materials, *Penstocks, Dam construction, Dams, Japan, Bulgaria, Yugoslavia.

Large-scale dams and power stations, particularly pumped-storage plants, require penstocks of larger diameters and strengths to cope with the higher heads of water currently being exploited. The characteristics, of various types of high tensile strength steel manufactured in Japan for large scale penstocks are described. The use of HT (high tensile) steel plates means that the allowable stress can be higher, and the wall thickness of the penstock can be reduced compared with lower strength steel plates. The reduction in wall thickness results in direct and indirect cost reductions and lead to economics in the following areas: transport and installation as the weight is less; fabrication and welding which will be easier; and material savings as less will be required. Penstock pipes can be classified according to shape. HT steel plates are either used for part or all of the penstock, depending on the maximum hydraulic pressure on each part of the pipes. Fundamental requirements for penstock plate quality include: weldability - low preheating temperature and high maximum heat input; workability; fracture toughness; and inner quality. Examples of HT steel applications are found in Bajina Basta, Yugoslavia; Chaira, Bulgaria; and Imaichi, Japan. (Baker-IVI)

DIRECTIONAL BLASTING IN ROCKFILL DAM CONSTRUCTION,
Vsesoyuznyi Nauchno-Issledovatel'skii Inst. Vodosnabzheniya, Kanalizatsii, Gidrotekhnicheskikh Sooruzhenii i Inzhenernoi Gidrogeologii, Moscow (USSR).
V. P. Nedriga, G. I. Pokrovsky, and N. P. Lushnov.
International Water Power and Dam Construction, Vol. 35, No. 6, p 37-40, June, 1983. 7 Fig, 1 Tab, 5 Ref.

Descriptors: *Excavation, *Dam construction, *Directional blasting, Reservoirs, Construction, Environmental effects, Economic factors, USSR.

Directional blasting is frequently used in dam construction in the mountainous regions of the USSR in order to shorten the construction time, reduce the labor content, provide considerable economies and help in the protection of soils in dams constructed by blasting operations. Those mountainous rivers favorably disposed to such treatment are characterized as follows: the gorge in the dam site is sufficiently narrow for the ratio of its width at the crest level to its height is not more than 2:3 with slopes of 30 degrees; the rock of the valley is suitable for placing in the dam body; the quantity of rock material which needs to be placed in the dam body must be somewhat higher than normal upper value with the optimum configuration within the construction site; and the sides of a valley must be easily cleared from humus, skeery and loose crumble. A homogeneous dam is a mass of rocks piled on the given site of a riverbed by directional blasting. Such dams usually have considerable permeability. A composite dam having face, or a face and a blanket is placed by both directional blasting in the downstream section and the usual operations used for transition zones, with faces of fine-grained and cohesive soils respectively. A hydroblasted dam consists of upstream and downstream sections placed by blasting, but the central core of impermeable soils is placed by hydraulic fill. Sometimes it is worthwhile constructing the antiseepage sections also with the help of directional blasting. The density of any coarse-grained material placed in a dam body depends on two factors: grain-size distribution of materials and methods of compaction. In this application the grain-size distribution of soils is characterized mainly by natural fissuration of the rock at the dam site, blasting operations and partly by the mechanical properties of the rock mass itself. The change in the grain-size because of falling after the explosion is insignificant and inherent in coarse rocks; in any case the amount is generally small. (Baker-IVI)

MORTALITY OF JUVENILE SALMONIDS PASSING THROUGH OSSBERGER CROSSFLOW TURBINES AT SMALL-SCALE HYDROELECTRIC SITES,
Cornell Univ., Ithaca, NY. Dept. of Natural Resources.
S. P. Gloss, and J. R. Wahl.
Transactions of the American Fisheries Society, Vol. 112, No. 2A, p 194-200, March, 1983. 4 Fig, 1 Tab, 10 Ref. 14-16-0009-80-1004.

Descriptors: *Turbines, *Mortality, *Salmon, *Trout, Fish migration, Fish size, Juvenile growth stages, Hydroelectric plants, Ossberger Crossflow turbine.

Experiments were conducted on Ossberger Crossflow turbines to determine the amount of mortality that would be incurred by downstream-migrating juvenile salmonids passing through these turbines. Species tested were Atlantic salmon Salmo salar, and rainbow trout and steelhead Salmo gairdneri. A highly significant ($P<0.01$) relationship between fish size and arc sine square root of mortality was found. Regression equations were calculated to predict expected mortality through 48 hours based upon size of fish. Mortality ranged from 15% for 85-mm fish to over 70% for 280-mm fish. No significant differences in mortality existed among similar size-groups of the three salmonids tested. Neither output of the turbine nor its size (650 versus 850 kilowatts) affected the amount of mortality. Temporal distribution of mortality after fish passed through the turbine was not different among species nor was it affected by the absolute rate of mortality in a given trial. Over 75% of the mortality was considered instantaneous. (Author's abstract)

LARVAL FISH TRANSPORT: A CASE STUDY OF WHITE BASS,
Tennessee Valley Authority, Knoxville. Div. of Water Resources.
L. B. Starnes, P. A. Hackney, and T. A. McDonough.
Transactions of the American Fisheries Society, Vol. 112, No. 3, p 390-397, May, 1983. 4 Fig, 1 Tab, 22 Ref.

Descriptors: *Larvae, *Fish behavior, Downstream transport, Velocity, Entrainment, Bass, Hydraulic transport, River flow.

Larval white bass Morone chrysops resisted downstream transport in the Holston River, eastern Tennessee. Despite a short hydraulic-transport time (<20 hours) through the study area (19.8 km), larvae were not transported downstream and out of this region soon after hatching. Recently hatched larvae were collected near a dam that blocks migration of spawning adults at the upper end of the study area; however, downstream from the dam larvae were significantly larger (and older) than expected if they had been transported passively through the area. Larval white bass pr ably remain near bottom or in other low-velo refugia that effectively reduce downstream placement. Hybrid striped bass Morone saxatil white bass larvae 4 mm and longer oriented stream in a laboratory flume; they swam orously and utilized areas of low current velo to reduce downstream displacement. Retar downstream transport found in the riverine e ronment, coupled with laboratory observatio implies that improvements are needed in mo used to estimate entrainment of fish larvae. MULTIPLE REGRESSION ANALYSIS F FORECASTING CRITICAL FISH INFLUX AT POWER STATION INTAKES,
Central Electricity Generating Board, Faw (England).
A. W. H. Turnpenny.
Journal of Applied Ecology, Vol. 20, No. 1, p 42, April, 1983. 4 Fig, 3 Tab, 12 Ref.

Descriptors: *Fish populations, *Entrainme *Powerplants, Cooling water, Regression anayl Statistical models, Fish impingement, Water te perature, Tides, Wind speed.

Certain coastal power stations in Britain are s ject to ingresses of fish which may jeopardize pl operation or which may cause temporary lo depletion of fish populations. There have b attempts in the United States and in Europe develop costly and often ineffectual exclusion vices. As an alternative, it is proposed that, sites where the problem is intermittent, statisti models should be developed which allow criti levels of fish ingress to be predicted and the nec sary reduction in cooling water flow determin The procedure for developing a multiple regr sion model is described and illustrated using f impingement data collected from Fawley Pow Station. Over 60% of the overall variation v accounted for in terms of a small number of eas measured variables (cooling water flow, wa temperature, tide height, wind speed). In ot research work, values of up to 80% have b quoted. With refinements of the model formulati higher values should be possible and the approa then would have practical application. (Autho abstract)
W84-01440

RESTORATION OF A DISUSED DOCK BAS AS A HABITAT FOR MARINE BENTHOS A FISH,
Liverpool Univ. (England). Hartley Botani Labs.
G. Russell, S. J. Hawkins, L. C. Evans, H. D. Jones, and G. D. Holmes.
Journal of Applied Ecology, Vol. 20, No. 1, p 58, April, 1983. 9 Fig, 1 Tab, 20 Ref.

Descriptors: *Estuarine environment, *Marine fi *Marine plants, Water quality, Habitats, Destrat cation, Salinity, Water temperature, Oxygenati Trace metals, Mytilus, Artificial habitats.

Changes in the water quality, and in flora a fauna, of a Liverpool dock have been monitor since closure of its gates in 1977. Water salinit have been found to fall within the range 25-31 and temperatures 0.3-19 degrees C. Secchi d extinction depths averaged 5-6 m in the dock a 10 cm in the Mersey estuary outside. An air- pump has been installed which prevents stratifi tion during summer and ensures an oxygen-ri water column. The absence of harmful dinoflag late blooms is attributed to artifical destratificati by this method. Improvements in water qual have been accompanied by the development o more diverse marine flora and fauna than in otl unclosed docks. The benthic community is dor nated by Mytilus edulis. Trace metal concent tions and coliform bacterial counts in Mytilus fle are sufficiently low for the animals to comply w existing food safety regulations. Introduced Lam aria saccharina grew until water temperatu reached 15 degrees C, but a few plants survive

eek period in summer 1981 when ambient r temperatures were above 15 degrees C. It is uded that a dock of this character can be ained as a productive marine environment a variety of educational, amenity and eco- uses. (Author's abstract)

GN OF HABITAT STRUCTURES FOR N CHANNELS,
Engineer Waterways Experiment Station, burg, MS. Environmental Lab.
Shields, Jr.
al of Water Resources Planning and Manage- Vol. 109, No. 4, p 331-344, October, 1983. 1 Tab, 32 Ref.

riptors: *Habitat structures, Aquatic habitats, Current deflectors, Boulders, Channel modifi- , Channeling, Stream biota.

any cases, channel modifications have ex- ly adverse impacts on aquatic communities. Rudimentary design guidelines are presented for simple structures (sills, current deflectors, and individual boulders) used to accelerate biological recovery of modified stream channels. These structures increase the physical habitat diversity of a modified channel. Data from nine case studies are presented in tabular form, including stream channel characteristics, structure dimensions, and an analysis of biological effectiveness and structural durability. Available literature on habitat structures focuses on applications to unenlarged cold-water streams with coarse bed material. Documented experience with enlarged warmwater streams that have poorly armored channels is extremely limited. (Author's abstract)

FINDING SALMON AND TROUT IN LAKE ONTARIO,
State Univ. of New York Coll. at Brockport.
J. M. Haynes.
Water Spectrum, Vol. 15, No. 1, p 30-37, Spring, 1983. 11 Fig.

Descriptors: *Fishing, *Lakes, *Telemetry, Data collecting, Fish, Population dynamics, Trout, Salmon, Lake fisheries, Water temperature.

Radiotelemetry and vertical gill netting were used to obtain knowledge about the whereabouts of some species of fish during certain seasons of the year in Lake Ontario. Particular attention was given to the chinook salmon. Salmon and trout move great distances during seasons when they are nearshore. Summer netting revealed that steelhead/rainbow trout and Pacific salmon are widely dispersed and far offshore, while lake and brown trout are concentrated in narrow temperature preference bands associated with the thermocline, lake bottom, and nearshore regions. It is felt that such studies will bring new research approaches to solve problems for the Great Lakes fishing industry and help in restoring economic and ecological health to the region. (Baker-IVI)

W84-01650 5A

HALOGENATED HYDROCARBONS
Determination of Halogenated Organic Compounds in Water by Gas Chromatography/Atmospheric Pressure Helium Microwave-Induced Plasma Emission Spectrometry with a Heated Discharge Tube for Pyrolysis,
W84-01584 5A

HAZARDOUS MATERIALS
Interaction of Clay Soils with Water and Organic Solvents: Implications for the Disposal of Hazardous Wastes,
W84-01500 5G

Organic Micropollutants in Water - a WHO Viewpoint,
W84-01566 5G

HEAD
Geostatistical Approach to the Trickle Irrigation Design in Heterogeneous Soil; 1. Theory,
W84-01706 2G

HEADWATER FLOODING
Urban Headwater Flooding Damage Potential,
W84-01534 2E

HEAT
Numerical Studies of the Heat and Mass Transport in the Cerro Prieto Geothermal Field, Mexico,
W84-01719 2F

HEAVY METALS
Heavy Metal Concentrations in Tissues of Virginia River Otters,
W84-01426 5C

Effects of Grays Harbor Estuary Sediment on the Osmoregulatory Ability of Coho Smolts (Oncorhynchus kisutch),
W84-01432 5B

Mobility in Soil and Plant Availability of Metals Derived from Incinerated Municipal Refuse,
W84-01495 5B

Application of Continuous-Flow Ultrafiltration and Competing Ligand/Differential Spectrophotometry For Measurement of Heavy Metals Complexation by Dissolved Organic Matter,
W84-01557 5A

Interferences of Major Elements in the Determination of Lead, Copper, Cadmium, Chromium and Nickel in River Sediments and Sewage Sludges by Electrothermal Atomic Absorption Spectrometry (Interferences des Elements Majeurs sur la Determination de Pb, Cu, Cd, Cr et Ni Dans les Sediments de Cours D'Eau et les Boues de Stations D'Epuration par Spectrometrie D'Absorption Atomique sans Flamme),
W84-01558 5A

Rapid Separation by Flotation of Suspended Solids in Fresh Waters for the Determination of Adsorbed Heavy Metals,
W84-01563 5A

Comparative Study of the Effects of Metals on the Settlement of Crassostrea gigas,
W84-01588 5C

Effects of Metals on Methanogenesis, Sulfate Reduction, Carbon Dioxide Evolution, and Microbial Biomass in Anoxic Salt Marsh Sediments,
W84-01656 5C

Speciation (Including Adsorbed Species) of Copper, Lead, Nickel and Zinc in the Meuse River; Observed Results Compared to Values Calculated with a Chemical Equilibrium Computer Program,
W84-01680 5B

Determination of Heavy Metals in Sediments by X-Ray Fluorescence in SEM (Qualitative and Quantitative Evaluation): Part 1:Technique (Qualitative und quantitative Rontgenanalyse von Schwermetallen in Sedimenten im REM durch Rontgenfluorescenz-Anregung Teil 1: Methodik),
W84-01735 5A

HEMICELLULOSE
Distribution of Hemicellulose-Decomposing Bacteria and Environmental Conditions in Seawater in Hiro Bay,
W84-01455 5C

HIGH FLOW
Stochastic Analysis of High Flows in Some Central British Columbia Rivers,
W84-01511 2E

HIGH-SPEED LIQUID CHROMATOGRAPHY
Application of High-Speed Liquid Chromatography using Solvent Extraction of the Molybdoheteropoly Yellow to the Determination of Microamounts of Phosphorus in Waste Waters,
W84-01730 5A

HUMAN DISEASES
Schistosomiasis and Water Projects: Breaking the Link,
W84-01728 6G

HUMAN PATHOLOGY
Neurologic Evaluation of a Population Exp to Arsenic in Alaskan Well Water,
W84-01604

HUMIC ACIDS
Characterization of Nonvolatile Aqueous C ination Products of Humic Substances,
W84-01493

Application of Van Krevelen's Graphical-S tical Method for the Study of Aquatic H Material,
W84-01508

HYDRAULIC ENGINEERING
Pressure Fluctuations on the Bottom of C Channel Turbulent Flows in Spillway S tures,
W84-01739

HYDRAULIC HEAD
A Geostatistical Approach to the Inverse P lem in Groundwater Modeling (Steady S and One-Dimensional Simulations,
W84-01710

HYDRAULIC JUMP
Internal Flow in Hydraulic Jumps,
W84-01542

HYDRAULIC MODELS
An Ephemeral Stream-Aquifer Intera Model,
W84-01704

HYDRAULIC PROPERTIES
Experiments to Assess the Hydraulic Effici of Well Screens,
W84-01547

HYDRAULICS
Characteristics Method Using Time-Line I polations,
W84-01541

The Hydraulics of Reservoir Sedimentation,
W84-01621

HYDROCARBONS
Effects of Crude Oil and Naphthalene Growth, Caloric Content, and Fat Conte Pink Salmon Juveniles in Seawater,
W84-01403

Distribution of Polycyclic Aromatic Hydr bons in the Surficial Sediments of Casco Maine,
W84-01433

Development of a Novel Method For Mon ing Oils In Water,
W84-01562

Levels of Organic Pollution in Coastal Lag of Tabasco State, Mexico; I: Petroleum Hy carbons,
W84-01585

Scale Morphologic Response to Aromatic drocarbons,
W84-01587

Toxicity, Accumultion and Clearance of matic Hydrocarbons in Daphnia pulex,
W84-01594

Qualitative and Quantitative Determinatio Dissolved Hydrocarbons in Water and S ments (Analyse Qualitative et Quantitative Traces d'Hydrocarbures Dissous Dans l'Ea Impregnant des Sediments),
W84-01612

DRODYNAMICS
article Size Reduction by Breakage in Biological Wastewater Treatment,
W84-01514 5D

DROELECTRIC PLANTS
arge Capacity Bulb Units in Japan,
W84-01613 8A

ientific Basis of the Designs of the Underound Structures of the Rogun Hydroelectric ation,
W84-01747 8E

n-Site Observation of the Concrete Structures the Kakhovka Hydroelectric Station,
W84-01750 8F

dvanced Engineering in the Design and Conuction of the Chirkey Hydroelectric Station,
W84-01751 8A

DROGEN ION CONCENTRATION
crobiological Survey of Adirondack Lakes th Various pH Values,
W84-01654 5C

DROGEN METABOLISM
dioassay for Hydrogenase Activity in Viable lls and Documentation of Aerobic Hydrogennsuming Bacteria Living in Extreme Environnts,
W84-01652 2H

drogen Metabolism by Decomposing Cyanoterial Aggregates in Big Soda Lake, Nevada,
W84-01653 2H

ROGEN PEROXIDE
erational Experience Using H2O2 in Landfill achate Treatment,
W84-01567 5E

ROGENASE
dioassay for Hydrogenase Activity in Viable ls and Documentation of Aerobic Hydrogennsuming Bacteria Living in Extreme Environnts,
W84-01652 2H

ROGRAPHY
e Hydrography and Phytoplankton Ecology Loch Ardbhair: A Small Sea-Loch on the st Coast of Scotland,
W84-01643 2L

ROLOGIC PROPERTIES
drologic Effects of Clearcutting and Wildfire Steep Granitic Slopes in Idaho,
W84-01723 4C

ROLOGICAL REGIME
drological Response Patterns of Some Third der Streams on the Basement Complex of thwestern Nigeria,
W84-01763 2E

ROXIDE
ste Sludge Treatment - More Performance Less Money,
W84-01565 5E

REAKUP
Breakup and Jamming Observations along Mackenzie River,
W84-01509 2C

STRIAL WASTES
of Fluorescence Spectroscopy for Monitor- Petroleum Hydrocarbon Contamination in arine and Ocean Waters,
W84-01425 5A

ntification of a Membrane Foulant in the ctrodialytic Recovery of Nickel,
W84-01577 5B

INDUSTRIAL WASTEWATER
Analysis of the Effect of Industrial Effluent on Pigments, Proteins, Nucleic Acids, and the 2,6-Dichlorophenol Indophenol Hill Reaction of Rice Seedlings,
W84-01602 5C

INDUSTRIAL WASTEWATERS
Chemical Changes in Concentrated, Acidic, Metal-Bearing Wastewaters When Treated with Lime,
W84-01496 5D

INDUSTRIAL WASTWATER
Pollution Control and Inputs to Production,
W84-01606 5G

Alternative Policy Instruments under Uncertainty: A Programming Model of Toxic Pollution Control,
W84-01609 5D

INFILTRATION
Aquifer Tests and Well Field Performance, Scioto River Valley, Ohio: Part I,
W84-01548 2F

The Influence of the Initial Water Content on the Redistribution of Soil Water after Infiltration,
W84-01599 5G

Rainwater Infiltration into a Bare Loamy Sand,
W84-01765 2G

INFILTRATION RATE
Effect of Low Levels of Exchangeable Sodium and Applied Phosphogypsum on the Infiltration Rate of Various Soils,
W84-01597 5G

INTERNAL FLOW
Internal Flow in Hydraulic Jumps,
W84-01542 8B

INTERSTITIAL WATER
Extraction and Chemical Analysis of Interstitial Water from Soils and Rocks,
W84-01505 2G

INVERTEBRATES
A Simple Toxicity Apparatus for Continuous Flow with Small Volumes: Demonstration with Mysids and Naphthalene,
W84-01424 7B

Comparative Acute Toxicities of Surfactants to Aquatic Invertebrates,
W84-01608 5C

INVESTMENT
Optimal Investment to Reduce the Decay Rate of an Income Stream: The Case of Soil Conservation,
W84-01607 5G

ION EXCHANGE
Reclamation of Wastewater Constituents by Ion Exchange, Part I. Review of Flowsheets for the Processes - continued from Volume 23 numbers 1 and 2,
W84-01568 5D

Reclamation of Wastewater Constituents by Ion Exchange; Part I Review of Flowsheets for the Processes - Continued from Volume 23 Numbers 1, 2 and 4,
W84-01572 5D

Reclamation of Wastewater Constituents by Ion Exchange; Part II Review of Contacting Equipment,
W84-01574 5D

IRON
Using By-Products of an Iron Removal Process to Improve Water Treatment,
W84-01531 5F

IRRIGATION DESIGN
Geostatistical Approach to the Trickle Irrigation Design in Heterogeneous Soil; 1. Theory,
W84-01706 2G

IRRIGATION EFFECTS
Gamma Neutron Method Applied to Field Measurement of Hydrodynamic Dispersion,
W84-01697 2G

ISOTACHOPHORESIS
Determination of Phenol in Industrial Waste Water by Isotachophoresis,
W84-01732 5A

ISOTHERMS
Partition Equilibria of Nonionic Organic Compounds between Soil Organic Matter and Water,
W84-01497 5B

ISOTOPE STUDIES
10Be and Be In the Maurice River-Union Lake System of Southern New Jersey,
W84-01488 2H

Temporal Distributions of Radiostrontium Isotopes and Radon Daughters in Rainwater During a Thunderstorm,
W84-01491 2K

ISOTOPIC TRACERS
Radioassay for Hydrogenase Activity in Viable Cells and Documentation of Aerobic Hydrogen-Consuming Bacteria Living in Extreme Environments,
W84-01652 2H

ITALY
Eutrophication Problems in Emilia Romagna, Italy,
W84-01670 5B

JETS
Hydraulic Loads on the Solid Boundary of a Flow Under the Effect of a Fragmented Jet,
W84-01753 8B

KINETICS
Kinetic Analysis of Strontium and Potassium Sorption onto Sands and Gravels in a Natural Channel,
W84-01715 2K

LAGOONS
Seasonal Diversity, Abundance, and Distribution of Ichthyoplankton in Tamiahua Lagoon, Western Gulf of Mexico,
W84-01404 2L

Organochlorine Residues in Organisms of Two Different Lagoons of Northwest Mexico,
W84-01428 5B

Levels of Organic Pollution in Coastal Lagoons of Tabasco State, Mexico; I: Petroleum Hydrocarbons,
W84-01585 5C

LAKE MICHIGAN
Distribution and Abundance of Larval Burbot and Deepwater Sculpin in Lake Michigan,
W84-01401 2H

LAKE SEDIMENTS
Chlorophyll a and Adenosine Triphosphate Levels in Antarctic and Temperate Lake Sediments,
W84-01472 2H

LAKES
Community Analysis in Fishery Management: An Application with Northern Wisconsin Lakes,
W84-01413 2H

Sedimentation in a Large Lake: A Reinterpretation of the Late Pleistocene Stratigraphy at Scarborough Bluffs, Ontario, Canada,
W84-01444 2J

Lake St. Clair: Since the Mercury Crisis,
W84-01640 5B

Finding Salmon and Trout in Lake Ontario,
W84-01641 8I

Initial Effects of the Mount St. Helens Eruption on Nitrogen Cycle and Related Chemical Processes in Ryan Lake,
W84-01657 2H

Sensitivity of Florida Lakes to Acidic Precipitation,
W84-01725 2H

LAND DISPOSAL
Land Applications of Wastewater: Water Rights Issues,
W84-01466 6E

Land Treatment of Hazardous Waste,
W84-01480 5E

Interaction of Clay Soils with Water and Organic Solvents: Implications for the Disposal of Hazardous Wastes,
W84-01500 5G

LANDFILLS
Operational Experience Using H2O2 in Landfill Leachate Treatment,
W84-01567 5E

Migration of Contaminants in Groundwater at a Landfill: A Case Study; 1. Groundwater Flow and Plume Delineation,
W84-01684 5B

Migration of Contaminants in Groundwater at a Landfill: A Case Study; 7. DC, VLF, and Inductive Resistivity Surveys,
W84-01690 5B

LARVAE
Distribution and Abundance of Larval Burbot and Deepwater Sculpin in Lake Michigan,
W84-01401 2H

Diel Drift and Feeding of Channel Catfish Alevins in the Illinois River, Arkansas,
W84-01409 2H

Identification of Catostomid Larvae in Pyramid Lake and the Truckee River, Nevada,
W84-01411 2H

Larval Fish Transport: A Case Study of White Bass,
W84-01415 8I

Comparative Study of the Effects of Metals on the Settlement of Crassostrea gigas,
W84-01588 5C

LEACHATES
Operational Experience Using H2O2 in Landfill Leachate Treatment,
W84-01567 5E

Identification of Organic Compounds in Leachate from a Waste Tip,
W84-01682 5B

Migration of Contaminants in Groundwater at a Landfill: A Case Study; 1. Groundwater Flow and Plume Delineation,
W84-01684 5B

LEACHING
Mobility in Soil and Plant Availability of Metals Derived from Incinerated Municipal Refuse,
W84-01495 5B

Competitive Adsorption During Solute Transport in Soils: 1. Mathematical Models,
W84-01596 2G

LEAD
Geochemical Factors Complicating the Use of Aufwuchs as a Biomonitor for Lead Levels in Two New Jersey Reservoirs,
W84-01678 5A

LEGAL ASPECTS
Ground-Water Management in Arizona,
W84-01461 4B

LEGISLATION
Arizona's Water Strategy: Bring More in and Restrict Its Use,
W84-01479 6D

LIME
Chemical Changes in Concentrated, Acidic, Metal-Bearing Wastewaters When Treated with Lime,
W84-01496 5D

LINEAR DIFFUSION
On Backwater Effects in Linear Diffusion Flood Routing,
W84-01764 2E

LOCHS
The Hydrography and Phytoplankton Ecology of Loch Ardbhair: A Small Sea-Loch on the West Coast of Scotland,
W84-01643 2L

LOCK GATES
Evaluation of Stresses in Elements of the Lock Gates on the Moscow Canal,
W84-01749 8C

LOCKS
Pile Selection and Design: Lock and Dam No. 26 (Replacement),
W84-01760 8A

LOGGING (RECORDING)
Geophysical Logging in Carbonate Aquifers,
W84-01554 2F

MALATHION
Malathion Induced Hematological and Biochemical Changes in the Indian Catfish Heteropneustes fossilis,
W84-01601 5C

MANGANESE
Using By-Products of an Iron Removal Process to Improve Water Treatment,
W84-01531 5F

MARINE FISH
Restoration of a Disused Dock Basin as a Habitat for Marine Benthos and Fish,
W84-01441 8I

MARINE PLANTS
Restoration of a Disused Dock Basin as a Habitat for Marine Benthos and Fish,
W84-01441 8I

MARINE SEDIMENTS
The Response of Interstitial Ammonium in Eelgrass (Zostera marina L.) Beds to Environmental Perturbations,
W84-01478 2L

MARSH PLANTS
The Effect of Nitrogen Fertilization on the Production of Halophytes in an Inland Salt Marsh,
W84-01450 2L

MASS BALANCE
Comparison of Denitrification Rate Estimation Techniques in a Large, Shallow Lake,
W84-01679 2H

MASS SPECTROMETRY
Factors Affecting the Accuracy of Quantitat
Analyses of Priority Pollutants Using GC/M
W84-01507

Precision and Accuracy in the Determinatio
Organics in Water by Fused Silica Capill
Column Gas Chromatography/Mass Spectro
etry and Packed Column Gas Chromatograp
Mass Spectrometry,
W84-01583

The Interpretation of Complex Chromatogra
by Computer Analysis,
W84-01673

A New Calibration Method for the Nit
Trace Determination in Water Samples (
neues Eichverfahren zur Nitrat-Spurenbes
mung in Wasserproben),
W84-01733

MASS TRANSFER
Kinetic Analysis of Strontium and Potass
Sorption onto Sands and Gravels in a Nat
Channel,
W84-01715

Simulation of Solute Transport in a Moun
Pool-and-Riffle Stream with a Kinetic M
Transfer Model for Sorption,
W84-01716

Numerical Studies of the Heat and Mass Tra
port in the Cerro Prieto Geothermal Fi
Mexico,
W84-01719

MATHEMATICAL MODELS
Technique for Calibrating Network Models,
W84-01471

A Model for the Density of Aeromonas hyd
phila in Albemarle Sound, North Carolina,
W84-01473

A Two-Dimensional Numerical Model of
tuarine Circulation Using Cubic Splines,
W84-01510

Dependence of Biological Treatment Rate
Species Composition in Activated Sludge
Biofilm. II: From Models to Theory,
W84-01517

Modeling of Unsteady-Flow Water Temp
tures,
W84-01540

Competitive Adsorption During Solute Tr
port in Soils: 1. Mathematical Models,
W84-01596

Estimating Soil Moisture Storage in the R
Zone from Surface Measurements,
W84-01598

The Excavation of Large Underground O
ings: A Numerical Simulation,
W84-01625

Simulation Model of the Water Balance
Cropped Soil: SWATRE,
W84-01694

Capacity Expansion Model for Large-S
Water-Energy Systems,
W84-01701

Incorporation of Prior Information on Par
eters into Nonlinear Regression Groundw
Flow Models; 2. Applications,
W84-01709

Estimating Spatial Variability in Soil Mois
with a Simplified Dynamic Model,
W84-01717

LIBRARY OF U. OF I. URBANA-CHAMPAIGN

upply-Based Models of Suspended Sediment Transport in Streams,
W84-01720 2K

unoff Prediction Errors and Bias in Parameter stimation Induced by Spatial Variability of recipitation,
W84-01722 2E

pplication of a Bayesian Model to Detect hifts in the Mean of a Series (Application d'un odele bayesien de detection de changements de oyennes dans une serie),
W84-01761 2E

ynamic Advective Water Quality Model for ivers,
W84-01767 5B

THEMATICAL STUDIES
lculation of a Local Scour Depression Near a otected Concave Bank of a Gravel-Pebble annel,
84-01738 8B

valuation of the Accuracy of Calculating the ability of Slopes of Earth Dams in Check lculations of Slopes that Failed,
84-01740 8D

e of the Method of Multipurpose Optimiz-on for Economic Justification of Hydropower stallations,
84-01741 6B

HANICAL EQUIPMENT
echanical Equipment for Dinorwic.
84-01620 8C

timization of Dredge and Variable Displace-nt Pumps,
84-01746 8C

provement of the Mechanical Equipment of gh-Head Spillways,

IBRANE PROCESSES
ntification of a Membrane Foulant in the ctrodialytic Recovery of Nickel,
4-01577 5B

CURY
rcury Distribution in an Ecosystem of the rque Nacional de Donana,' Spain,
4-01435 5B

e St. Clair: Since the Mercury Crisis,
4-01640 5B

ABOLISM
ticide-Induced Dysfunction in Carbohydrate tabolism in Three Freshwater Fishes,
4-01603 5C

hanogenesis from Methanol and Methyla-es and Acetogenesis from Hydrogen and bon Dioxide in the Sediments of a Eutrophic e,
4-01648 2H

cts of Metals on Methanogenesis, Sulfate uction, Carbon Dioxide Evolution, and Mi-bial Biomass in Anoxic Salt Marsh Sedi-ts,
4-01656 5C

AL COMPLEXES
lication of Continuous-Flow Ultrafiltration Competing Ligand/Differential Spectropho-etry For Measurement of Heavy Metals plexation by Dissolved Organic Matter,
4-01557 5A

plexation Analysis of Fresh Waters by ilibrium Diafiltration,
4-01671 2K

METAL FINISHING WASTES
Reclamation of Wastewater Constituents by Ion Exchange, Part I. Review of Flowsheets for the Processes - continued from Volume 23 numbers 1 and 2,
W84-01568 5D

METALS
X-Ray Microanalysis of Planktic Diatoms in in situ Studies of Metal Pollution,
W84-01476 5A

Determination of Heavy Metals in Sediments by X-Ray Fluorescence in SEM (Qualitative and Quantitative Evaluation); Part 2: Application (Qualitative und quantitative Rontgenanalyse von Schwermetallen in Sedimenten im REM durch Rontgenfluorescenz-Anregung; Teil 2: Anwendung),
W84-01736 5A

METHANOGENESIS
Methanogenesis from Methanol and Methylamines and Acetogenesis from Hydrogen and Carbon Dioxide in the Sediments of a Eutrophic Lake,
W84-01648 2H

METHOD OF CHARACTERISTICS
Characteristics Method Using Time-Line Interpolations,
W84-01541 8B

MICROBIAL DEGRADATION
Distribution of Hemicellulose-Decomposing Bacteria and Environmental Conditions in Seawater in Hiro Bay,
W84-01455 5C

Microbial Transformation of Nitroaromatic Compounds in Sewage Effluent,
W84-01647 5B

MICROORGANISMS
A Note on the Effects of Crude Oil on Microbial Activities in a Stream Sediment,
W84-01592 5C

Reductive Dehalogenations of Halobenzoates by Anaerobic Lake Sediment Microorganisms,
W84-01650 5A

Microbiological Survey of Adirondack Lakes with Various pH Values,
W84-01654 5C

Effects of Metals on Methanogenesis, Sulfate Reduction, Carbon Dioxide Evolution, and Microbial Biomass in Anoxic Salt Marsh Sediments,
W84-01656 5C

MINE DRAINAGE
Pore-Water Pressure in the Roof of an Underground Coal Mine in Illinois,
W84-01551 2F

Particulate Forms of Radium and Barium in Uranium Mine Waste Waters and Receiving River Waters,
W84-01677 5A

MINE WASTES
Slaking Modes of Geologic Materials and Their Impact on Embankment Stabilization,
W84-01759 5B

MISSISSIPPI RIVERS
Distribution of Larval Fishes Related to Potential Navigation Impacts on the Upper Mississippi River, Pool 7,
W84-01408 6G

MODEL STUDIES
The Excavation of Large Underground Openings: A Numerical Simulation,
W84-01625 8D

A Stochastic-Dynamic Model for Real Time Flood Forecasting,
W84-01718 2E

MOISTURE STRESS
Effect of Summer Moisture Stress on the Capacity of Tansy Ragwort (Senecio jacobaea) to Compensate for Defoliation by Cinnabar Moth (Tyria jacobaeae),
W84-01442 2I

MOLLUSKS
Accumulation of Seven Metals by Crassostrea gigas, Crassostrea margaritacea, Perna perna, and Choromytilus meridionalis,
W84-01422 5B

MONITORING
Detection Limits of a Biological Monitoring System for Chemical Water Pollution Based on Mussel Activity,
W84-01423 5A

Use of Fluorescence Spectroscopy for Monitoring Petroleum Hydrocarbon Contamination in Estuarine and Ocean Waters,
W84-01425 5A

Development of a Novel Method For Monitoring Oils In Water,
W84-01562 5A

Geochemical Factors Complicating the Use of Aufwuchs as a Biomonitor for Lead Levels in Two New Jersey Reservoirs,
W84-01678 5A

Migration of Contaminants in Groundwater at a Landfill: A Case Study; 2. Groundwater Monitoring Devices,
W84-01685 5B

MONSOONS
Himalayan Winter Snow Cover Area and Summer Monsoon Rainfall over India,
W84-01490 2B

MORTALITY
Mortality of Juvenile Salmonids Passing through Ossberger Crossflow Turbines at Small-Scale Hydroelectric Sites,
W84-01402 8I

Alkyl Lead Pollution and Bird Mortalities on the Mersey Estuary, UK, 1979-1981,
W84-01595 5C

MOUNT ST. HELENS
Initial Effects of the Mount St. Helens Eruption on Nitrogen Cycle and Related Chemical Processes in Ryan Lake,
W84-01657 2H

MOUNTAIN STREAMS
Simulation of Solute Transport in a Mountain Pool-and-Riffle Stream: A Transient Storage Model,
W84-01714 2E

MUSSELS
Detection Limits of a Biological Monitoring System for Chemical Water Pollution Based on Mussel Activity,
W84-01423 5A

MUTAGENICITY
Mutagenicity of Municipal Sewage Sludges of American Cities,
W84-01499 5E

MUTAGENS
Structure Elucidation of 3-(2-Chloroethoxy)1,2-dichloropropene, a New Promutagen from an Old Drinking Water Residue,
W84-01502 5B

NATURAL WATERS
Investigation of the Folin-Ciocalteau Phenol Reagent for the Determination of Polyphenolic Substances in Natural Waters,
W84-01672 2K

NAVIGATION
Distribution of Larval Fishes Related to Potential Navigation Impacts on the Upper Mississippi River, Pool 7,
W84-01408 6G

NEGATIVE PRESSURE
Pressures on Spillway Aprons Downstream from Partly Raised Crest Gates,
W84-01487 8B

NEUTRALIZATION
Chemical Changes in Concentrated, Acidic, Metal-Bearing Wastewaters When Treated with Lime,
W84-01496 5D

NEUTRON ACTIVATION ANALYSIS
Preconcentration of Trace Elements in Natural Water with Cellulose Piperazinedithiocarboxylate and Determination by Neutron Activation Analysis,
W84-01582 5A

NITRATE
Nitrate in British Waters,
W84-01456 5G

Nitrate in the Netherlands - A Serious Threat to Groundwater,
W84-01457 5G

NITRATES
Acclimation of Channel Catfish (Ictalurus punctatus) to Nitrate,
W84-01431 5C

Nitrates Concentration Reduction in Drinking Water: Extra Details on Biological Treatments (Reduction des Teneurs en Nitrates dans les Eaux de Consommation: Le Point sur les Traitements Biologiques),
W84-01458 5F

Nitrate in Waters for Human Consumption: The Situation in France (1979-1981). A Study by the French Ministry of Health, (Teneur en Nitrate des Eauz Destinees a la Consommation Humaine: La Situation en France (1979-1981). Etude Realisee par le Ministere de la Sante Francais: Cadre de l'Etude).
W84-01460 5G

An Integrated Approach to Hydrogeologic Investigations - A Case History,
W84-01692 2F

A New Calibration Method for the Nitrate Trace Determination in Water Samples (Ein neues Eichverfahren zur Nitrat-Spurenbestimmung in Wasserproben),
W84-01733 5A

NITRIFICATION
Population Ecology of Nitrifiers in a Stream Receiving Geothermal Inputs of Ammonium,
W84-01646 2H

NITROAROMATIC COMPOUNDS
Microbial Transformation of Nitroaromatic Compounds in Sewage Effluent,
W84-01647 5B

NITROGEN
The Effect of Nitrogen Fertilization on the Production of Halophytes in an Inland Salt Marsh,
W84-01450 2L

NITROGEN CYCLE
Initial Effects of the Mount St. Helens Eruption on Nitrogen Cycle and Related Chemical Processes in Ryan Lake,
W84-01657 2H

NITROGEN REMOVAL
Eutrophication Problems in Emilia Romagna, Italy,
W84-01670 5B

NONIONIC SURFACTANTS
Determination of Traces of Polyoxyethylene Non-Ionic Surfactants in Water by Solvent Extraction-Spectrophotometry,
W84-01731 5A

NUTRIENTS
Studies of a Spring Phytoplankton Bloom in an Enclosed Experimental Ecosystem. I. Biochemical Changes in Relation to the Nutrient Chemistry of Water,
W84-01642 5C

Eutrophication Problems in Emilia Romagna, Italy,
W84-01670 5B

Report on Eutrophication Studies in the U.S.S.R.,
W84-01676 5C

ODOR CONTROL
Odour Control in Solid Waste Management,
W84-01564 5D

Operational Experience Using H2O2 in Landfill Leachate Treatment,
W84-01567 5E

OIL
Effects of Crude Oil and Naphthalene on Growth, Caloric Content, and Fat Content of Pink Salmon Juveniles in Seawater,
W84-01403 5C

OIL POLLUTION
Levels of Organic Pollution in Coastal Lagoons of Tabasco State, Mexico; I: Petroleum Hydrocarbons,
W84-01585 5C

A Note on the Effects of Crude Oil on Microbial Activities in a Stream Sediment,
W84-01592 5C

OLIGOTROPHIC LAKES
Microbiological Survey of Adirondack Lakes with Various pH Values,
W84-01654 5C

OLIVE OIL
Treatment of Olive Oil Wastes by Distillation,
W84-01576 5D

OOCYSTIS
Ingestion and Assimilation Rates of Oocystis sp. by Daphnia magna in Treated Wastewaters,
W84-01590 5D

ORGANIC COMPOUNDS
Land Treatment of Hazardous Waste,
W84-01480 5E

Organic Micropollutants in Water - a WHO Viewpoint,
W84-01566 5G

Cation-Exchange Concentration of Basic Organic Compounds from Aqueous Solution,
W84-01581 5A

Precision and Accuracy in the Determination of Organics in Water by Fused Silica Capillary Column Gas Chromatography/Mass Spectrometry and Packed Column Gas Chromatography/Mass Spectrometry,
W84-01583 5A

Identification of Organic Compounds in Leac ate from a Waste Tip,
W84-01682

ORGANIC MATTER
Seasonal Variation of Cadmium Toxicity towa the Alga Selenastrum capricornutum Printz Two Lakes with Different Humus Content,
W84-01504

Application of Continuous-Flow Ultrafiltrati and Competing Ligand/Differential Spectropl tometry For Measurement of Heavy Met Complexation by Dissolved Organic Matter,
W84-01557

Interbiome Comparison of Stream Ecosyst Dynamics,
W84-01644

ORGANOPHOSPHATES
Survival and Condition of Rainbow Tro (Salmo gairdneri) After Exposures to Meth Parathion, Triphenyl Phosphate, and DEF,
W84-01438

OTTERS
Heavy Metal Concentrations in Tissues of V ginia River Otters,
W84-01426

OVERLAND FLOW
Effects of Soil Properties on Overland Flow a Infiltration,
W84-01484

OXYGEN DEMAND
An in situ Sediment Oxygen Demand Sampl
W84-01675

OXYGEN METABOLISM
The Annual Pattern and Spatial Distribution Aquatic Oxygen Metabolism in Boreal For Watersheds,
W84-01645

OYSTERS
Comparative Study of the Effects of Metals the Settlement of Crassostrea gigas,
W84-01588

OZONATION
Preozonation as a Coagulant Aid in Drinki Water Treatment,
W84-01530

PARASITES
Schistosomiasis and Water Projects: Breaki the Link,
W84-01728

PARTICLE SIZE
Development and Prediction of Bed Armori
W84-01539

Particle-Size Distribution and Phospho Levels in Soil, Sediment, and Urban Dust a Dirt Samples from the Menomonee River W tershed, Wisconsin, U.S.A.,
W84-01674

PARTICULATES
Particulate Forms of Radium and Barium Uranium Mine Waste Waters and Receivi River Waters,
W84-01677

PARTITION
Partition Equilibria of Nonionic Organic Co pounds between Soil Organic Matter and Wat
W84-01497

Partitioning of Strontium-90 among Aquec and Mineral Species in a Contaminated Aquif
W84-01498

LIBRARY U. OF I. URBANA-CHAMPAIGN

H OF POLLUTANTS
igration of Contaminants in Groundwater at a ndfill: A Case Study; 5. Cation Migration in e Dispersion Test,
84-01688 5B

igration of Contaminants in Groundwater at a ndfill: A Case Study; 7. DC, VLF, and Induce Resistivity Surveys,
84-01690 5B

the Behavior of Environmental Pollutants in tificial Aquifers (Zum Verhalten von Umltchemikalien in kunstlichen Grundwasserger-en),
84-01734 5B

STOCKS
gh Tensile Strength Steel for Penstocks,
84-01614 8G

TACHLOROPHENOL
tivated Sludge Treatment of Synthetic stewater Containing Pentachlorophenol,
4-01757 5D

MEABILITY
Geostatistical Approach to the Inverse Prob- in Groundwater Modeling (Steady State) One-Dimensional Simulations,
4-01710 2F

MEABILITY COEFFICIENT
ostatistical Approach to the Trickle Irrigation ign in Heterogeneous Soil; 1. Theory,
4-01706 2G

MITS
nsferable Discharge Permit Trading under ying Stream Conditions: A Simulation of tiperiod Permit Market Performance on the River, Wisconsin,
4-01702 6E

CIDE RESIDUES
of Ethion in Canals Draining a Florida us Grove,
4-01556 5B

mparative Bioaccumulation and Elimination CH Isomers in Short-necked Clam (Venerujaponica) and Guppy (Poecilia reticulata),
-01589 5C

CIDES
nochlorine Residues in Organisms of Two erent Lagoons of Northwest Mexico,
-01428 5B

cts of Pesticides on Pure and Mixed Species ures of Salt Marsh Pool Algae,
-01429 4A

cide-Induced Dysfunction in Carbohydrate bolism in Three Freshwater Fishes,
-01603 5C

OL
rmination of Phenol in Industrial Waste r by Isotachophoresis,
-01732 5A

OLS
stigation of the Folin-Ciocalteau Phenol ent for the Determination of Polyphenolic ances in Natural Waters,
01672 2K

PHATES
ionation of Phosphorus and Releasable ion in Sediment Mud of Osaka Bay,
01454 5B

PHORUS
rmination of Phosphorus in Natural Waters ong-Capillary-Cell Absorption Spectrom-

01578 5A

Determination of Arsenic and Phosphorus Compounds in Groundwater with Reduced Molybdenum Blue,
W84-01580 5A

Particle-Size Distribution and Phosphorus Levels in Soil, Sediment, and Urban Dust and Dirt Samples from the Menomonee River Watershed, Wisconsin, U.S.A.,
W84-01674 5B

Application of High-Speed Liquid Chromatography using Solvent Extraction of the Molybdoheteropoly Yellow to the Determination of Microamounts of Phosphorus in Waste Waters,
W84-01730 5A

PHOSPHORUS REMOVAL
Eutrophication Problems in Emilia Romagna, Italy,
W84-01670 5B

PHYTOPLANKTON
The Hydrography and Phytoplankton Ecology of Loch Ardbhair: A Small Sea-Loch on the West Coast of Scotland,
W84-01643 2L

PILES
Pile Selection and Design: Lock and Dam No. 26 (Replacement),
W84-01760 8A

PIPE LININGS
Tetrachloroethylene Leached From Lined Asbestos-Cement Pipe into Drinking Water,
W84-01522 5F

PIPE ROUGHNESS
Technique for Calibrating Network Models,
W84-01471 8A

PIPELINES
For a Reliable Water Supply, Cost Comes Second.
W84-01668 4A

PLANKTON
Seasonal Diversity, Abundance, and Distribution of Ichthyoplankton in Tamiahua Lagoon, Western Gulf of Mexico,
W84-01404 2L

Comparison of Two Ichthyoplankton Sampling Gears with Notes on Microdistribution of Fish Larvae in a Large River,
W84-01406 7B

Estimating Bacterioplankton Production by Measuring (3H)Thymidine Incorporation in a Eutrophic Swedish Lake,
W84-01658 2H

PLANNING
Water Resource and the Environment: Development Planning in Brazil,
W84-01629 6G

Impact Studies for Dams and Reservoirs,
W84-01630 6G

PLANT PATHOLOGY
Analysis of the Effect of Industrial Effluent on Pigments, Proteins, Nucleic Acids, and the 2,6-Dichlorophenol Indophenol Hill Reaction of Rice Seedlings,
W84-01602 5C

POLLUTANT IDENTIFICATION
An Improvement for the Concentration of Micropollutants in the Marine Environment by Using a Bacteria Strain with a Membrane Filter System,
W84-01418 5A

Detection Limits of a Biological Monitoring System for Chemical Water Pollution Based on Mussel Activity,
W84-01423 5A

Distribution of Polycyclic Aromatic Hydrocarbons in the Surficial Sediments of Casco Bay, Maine,
W84-01433 5B

POLLUTANT MIGRATION
Migration of Contaminants in Groundwater at a Landfill: A Case Study; 1. Groundwater Flow and Plume Delineation,
W84-01684 5B

POLLUTANTS
Factors Affecting the Accuracy of Quantitative Analyses of Priority Pollutants Using GC/MS,
W84-01507 2A

POLLUTION LOAD
Eutrophication Problems in Emilia Romagna, Italy,
W84-01670 5B

PORE PRESSURE
Pore-Water Pressure in the Roof of an Underground Coal Mine in Illinois,
W84-01551 2F

POROUS MEDIA
Efficient Finite Element Technique for Modeling Transport in Fractured Porous Media; 1. Single Species Transport,
W84-01726 2F

POTASSIUM
Kinetic Analysis of Strontium and Potassium Sorption onto Sands and Gravels in a Natural Channel,
W84-01715 2K

POWERPLANTS
Multiple Regression Analysis for Forecasting Critical Fish Influxes at Power Station Intakes,
W84-01440 8I

Wetfall Chemistry Studies around a Large Coal-Fired Power Plant in the Southeastern United States,
W84-01492 5B

On-Site Investigations of the Hydraulic Regimes of a Transition Structure,
W84-01744 8B

PROCESS WATER
Factors Regulating the Density of Bacteria in Process Waters of a Paper Mill,
W84-01766 5D

PULP AND PAPER INDUSTRY
Factors Regulating the Density of Bacteria in Process Waters of a Paper Mill,
W84-01766 5D

PULP WASTES
Distribution of Hemicellulose-Decomposing Bacteria and Environmental Conditions in Seawater in Hiro Bay,
W84-01455 5C

PUMP TURBINES
The World's Highest Head Pump Turbines,
W84-01618 8C

Advances in Pump-Turbines Design,
W84-01619 8C

PUMPED STORAGE
First Pumped-Storage Scheme for the Philippines,
W84-01617 8C

Mechanical Equipment for Dinorwic.
W84-01620 8C

PUMPS
Optimization of Dredge and Variable Displacement Pumps,
W84-01746 8C

RADIOACTIVE WASTES
Improved Evaporators for Radioactive Wastes,
W84-01665 5D

RADIOISOTOPES
Seasonal Variation in the Accumulation of Radionuclides of the Uranium Series by Yellow Pond-Lily (Nuphar lutea),
W84-01436 2K

RADIUM
Particulate Forms of Radium and Barium in Uranium Mine Waste Waters and Receiving River Waters,
W84-01677 5A

RAFTING
Managing Rafting Rivers,
W84-01639 6D

RAINFALL
Himalayan Winter Snow Cover Area and Summer Monsoon Rainfall over India,
W84-01490 2B

Rainwater Infiltration into a Bare Loamy Sand,
W84-01765 2G

RAINFALL IMPACT
Rainwater Infiltration into a Bare Loamy Sand,
W84-01765 2G

RAINFALL-RUNOFF RELATIONSHIPS
Parameter Estimation in Rainfall-Runoff Models,
W84-01699 2E

Runoff Prediction Errors and Bias in Parameter Estimation Induced by Spatial Variability of Precipitation,
W84-01722 2E

RAINWATER
Temporal Distributions of Radiostrontium Isotopes and Radon Daughters in Rainwater During a Thunderstorm,
W84-01491 2K

RECLAIMED WATER
Reclamation of Wastewater Constituents by Ion Exchange, Part I. Review of Flowsheets for the Processes - continued from Volume 23 numbers 1 and 2,
W84-01568 5D

RECREATION DEMAND
Managing Rafting Rivers,
W84-01639 6D

RECYCLING
Reclamation of Wastewater Constituents by Ion Exchange; Part I Review of Flowsheets for the Processes - Continued from Volume 23 Numbers 1, 2 and 4,
W84-01572 5D

Reclamation of Wastewater Constituents by Ion Exchange; Part II Review of Contacting Equipment,
W84-01574 5D

REDISTRIBUTION
The Influence of the Initial Water Content on the Redistribution of Soil Water after Infiltration,
W84-01599 5G

REGULATION
Alternative Policy Instruments under Uncertainty A Programming Model of Toxic Pollution Control,
W84-01609 5D

REGULATIONS
Nitrate in Waters for Human Consumption: The Situation in France (1979-1981). A Study by the French Ministry of Health, (Teneur en Nitrate des Eauz Destinees a la Consommation Humaine: La Situation en France (1979-1981). Etude Realisee par le Ministere de la Sante Francais: Cadre de l'Etude).
W84-01460 5G

Soil Erosion: Economic and Technological Interfaces,
W84-01611 4D

REINFORCED CONCRETE
Constructing the Drakensberg Pressure Tunnels,
W84-01623 8A

RESERVOIR MANAGEMENT
Data Automation for Water Supply Management,
W84-01464 7B

RESERVOIR OPERATION
Reservoir Operation by Linear and Dynamic Programming,
W84-01467 4A

Reservoir Management: A Reliability Programming Approach,
W84-01703 4A

Application of a Bayesian Model to Detect Shifts in the Mean of a Series (Application d'un modele bayesien de detection de changements de moyennes dans une serie),
W84-01761 2E

RESERVOIR RELEASES
Reservoir Management: A Reliability Programming Approach,
W84-01703 4A

RESERVOIRS
Axisymmetric Vertical Circulation in a Stratified Reservoir,
W84-01483 2H

The Hydraulics of Reservoir Sedimentation,
W84-01621 2J

Reversing the Flow of Soviet Rivers.
W84-01622 3B

The Tucurui Experience,
W84-01627 6G

Impact Studies for Dams and Reservoirs,
W84-01630 6G

Found Water at 200 Gallons/Yard.
W84-01669 3B

RESISTIVITY
Migration of Contaminants in Groundwater at a Landfill: A Case Study; 7. DC, VLF, and Inductive Resistivity Surveys,
W84-01690 5B

RESOURCES DEVELOPMENT
Capacity Expansion Model for Large-Scale Water-Energy Systems,
W84-01701 6D

REVIEWS
Acid Rain: Filtering Out the Facts,
W84-01610 5C

RIPARIAN WATER LOSS
Estimation of Streamflow Loss by Evapotranspiration from a Riparian Zone,
W84-01443 2D

RIVER FLOW
Stochastic Analysis of High Flows in Some Central British Columbia Rivers,
W84-01511 2E

ROCK PROPERTIES
Scientific Basis of the Designs of the Underground Structures of the Rogun Hydroelectric Station,
W84-01747

ROCKFILL DAMS
Foundation Treatment for India's Salal Da
W84-01637

ROLLED CONCRETE
Experience in the Use of Rolled Concrete,
W84-01615

ROOTS
Estimating Soil Moisture Storage in the Ro Zone from Surface Measurements,
W84-01598

Simulation Model of the Water Balance of Cropped Soil: SWATRE,
W84-01694

RUNOFF
Why Not Charge for Storm Drainage,
W84-01667

RURAL AREAS
Organizing and Managing South Dakota's Ru Water Systems,
W84-01519

SALINE WATER
Origin of Dissolved Solids in Groundwaters Mayne Island, British Columbia, Canada,
W84-01693

SALMON
Mortality of Juvenile Salmonids Passing throu Ossberger Crossflow Turbines at Small-Sca Hydroelectric Sites,
W84-01402

Effects of Crude Oil and Naphthalene Growth, Caloric Content, and Fat Content Pink Salmon Juveniles in Seawater,
W84-01403

Effects of Grays Harbor Estuary Sediment the Osmoregulatory Ability of Coho Smo (Oncorhynchus kisutch),
W84-01432

SALMONELLA
Longevity of Salmonella typhimurium in Tila aurea and Water from Pools Fertilized wi Swine Waste,
W84-01655

SALT MARSHES
The Effect of Nitrogen Fertilization on the Pr duction of Halophytes in an Inland Salt Mars
W84-01450

Effects of Metals on Methanogenesis, Sulf Reduction, Carbon Dioxide Evolution, and M crobial Biomass in Anoxic Salt Marsh Se ments,
W84-01656

SAMPLING
Comparison of Two Ichthyoplankton Sampli Gears with Notes on Microdistribution of F Larvae in a Large River,
W84-01406

Sampling Strategy for Detecting Viruses in Sewage Treatment Plant,
W84-01659

An in situ Sediment Oxygen Demand Sampl
W84-01675

Migration of Contaminants in Groundwater a Landfill: A Case Study; 2. Groundwater Mo toring Devices,
W84-01685

ISTOSOMIASIS
nistosomiasis and Water Projects: Breaking Link,
4-01728 6G

JR
osion near Groyne-Like Structures,
4-01486 8B

LPIN
tribution and Abundance of Larval Burbot Deepwater Sculpin in Lake Michigan,
4-01401 2H

ONAL VARIATION
drological Response Patterns of Some Third ler Streams on the Basement Complex of thwestern Nigeria,
4-01763 2E

ONAL VARIATIONS
sonal Variation in the Accumulation of Ra-nuclides of the Uranium Series by Yellow d-Lily (Nuphar lutea),
4-01436 2K

MENT ANALYSIS
litative and Quantitative Determination of solved Hydrocarbons in Water and Sedi-ts (Analyse Qualitative et Quantitative de ces d'Hydrocarbures Dissous Dans l'Eau et regnant des Sediments),
4-01612 5A

ermination of Heavy Metals in Sediments by ay Fluorescence in SEM (Qualitative and ntitative Evaluation): Part 1:Technique litative und quantitative Rontgenanalyse Schwermetallen in Sedimenten im REM h Rontgenfluorescenz-Anregung Teil 1: nodik),
-01735 5A

ermination of Heavy Metals in Sediments by ay Fluorescence in SEM (Qualitative and ntitative Evaluation); Part 2: Application litative und quantitative Rontgenanalyse Schwermetallen in Sedimenten im REM h Rontgenfluorescenz-Anregung; Teil 2: endung),
-01736 5A

IENT EROSION
ability of Sediment Removal in a Semiarid rshed,
-01707 2J

IENT TRANSPORT
Transformations in Sediment Gravity s,
01445 2E

odified Einstein Procedure For Sediment ,
01536 2J

Dimensional Bed Wave Movement in Low-Rivers,
01705 2J

ly-Based Models of Suspended Sediment sport in Streams,
01720 2K

ENTATION
nentation in a Large Lake: A Reinterpreta-of the Late Pleistocene Stratigraphy at orough Bluffs, Ontario, Canada,
01444 2J

Hydraulics of Reservoir Sedimentation,
01621 2J

ENTS
bution of Polycyclic Aromatic Hydrocar-in the Surficial Sediments of Casco Bay, e,
01433 5B

Fractionation of Phosphorus and Releasable Fraction in Sediment Mud of Osaka Bay,
W84-01454 5B

Interferences of Major Elements in the Determination of Lead, Copper, Cadmium, Chromium and Nickel in River Sediments and Sewage Sludges by Electrothermal Atomic Absorption Spectrometry (Interferences des Elements Majeurs sur la Determination de Pb, Cu, Cd, Cr et Ni Dans les Sediments de Cours D'Eau et les Boues de Stations D'Epuration par Spectrometrie D'Absorption Atomique sans Flamme),
W84-01558 5A

Methanogenesis from Methanol and Methylamines and Acetogenesis from Hydrogen and Carbon Dioxide in the Sediments of a Eutrophic Lake,
W84-01648 2H

Effects of Metals on Methanogenesis, Sulfate Reduction, Carbon Dioxide Evolution, and Microbial Biomass in Anoxic Salt Marsh Sediments,
W84-01656 5C

SEEPAGE
Design of Cut Slopes in Overconsolidated Clays,
W84-01758 8D

SEMIARID LANDS
Variability of Sediment Removal in a Semiarid Watershed,
W84-01707 2J

SHADE
Effect of Transient, Partial-Area Shading on Evaporation from a Bare Soil,
W84-01600 2D

SIMULATION
Ground-Water Systems Simulation by Time-Series Techniques,
W84-01550 2F

Estimating Soil Moisture Storage in the Root Zone from Surface Measurements,
W84-01598 2G

SLAKING
Slaking Modes of Geologic Materials and Their Impact on Embankment Stabilization,
W84-01759 5B

SLOPE
Rainwater Infiltration into a Bare Loamy Sand,
W84-01765 2G

SLOPE STABILITY
Design of Cut Slopes in Overconsolidated Clays,
W84-01758 8D

SLOPES
Hydrologic Effects of Clearcutting and Wildfire on Steep Granitic Slopes in Idaho,
W84-01723 4C

SLUDGE
Mutagenicity of Municipal Sewage Sludges of American Cities,
W84-01499 5E

Interferences of Major Elements in the Determination of Lead, Copper, Cadmium, Chromium and Nickel in River Sediments and Sewage Sludges by Electrothermal Atomic Absorption Spectrometry (Interferences des Elements Majeurs sur la Determination de Pb, Cu, Cd, Cr et Ni Dans les Sediments de Cours D'Eau et les Boues de Stations D'Epuration par Spectrometrie D'Absorption Atomique sans Flamme),
W84-01558 5A

SLUDGE LAGOONS
Found Water at 200 Gallons/Yard.
W84-01669 3B

SLUDGE THICKENING
Waste Sludge Treatment - More Performance for Less Money,
W84-01565 5E

SNOW COVER
Himalayan Winter Snow Cover Area and Summer Monsoon Rainfall over India,
W84-01490 2B

SNOW DEPTHS
Snow as a Factor in Salt Desert Shrub Vegetation Patterns in Curlew Valley, Utah,
W84-01451 2I

SODIUM
Effect of Low Levels of Exchangeable Sodium and Applied Phosphogypsum on the Infiltration Rate of Various Soils,
W84-01597 5G

SODIUM SULFITE
Water Dechlorination by Activated Carbon, Ultraviolet Radiation and Sodium Sulphite; A Comparison of Treatment Systems Suitable for Fish Culture,
W84-01681 5F

SOIL
Mercury Distribution in an Ecosystem of the 'Parque Nacional de Donana,' Spain,
W84-01435 5B

SOIL CONSERVATION
Optimal Investment to Reduce the Decay Rate of an Income Stream: The Case of Soil Conservation,
W84-01607 5G

SOIL CRUST
Effect of Low Levels of Exchangeable Sodium and Applied Phosphogypsum on the Infiltration Rate of Various Soils,
W84-01597 5G

SOIL EROSION
Soil Erosion: Economic and Technological Interfaces,
W84-01611 4D

SOIL MECHANICS
Repetitive-Load Behavior of Unsaturated Soils,
W84-01755 2D

SOIL ORGANIC MATTER
Partition Equilibria of Nonionic Organic Compounds between Soil Organic Matter and Water,
W84-01497 5B

SOIL PROPERTIES
Adsorption of Fenitrothion and 3-Methyl-4-Nitrophenol on Soils and Sediment,
W84-01439 5B

Effects of Soil Properties on Overland Flow and Infiltration,
W84-01484 2E

SOIL SATURATION
Repetitive-Load Behavior of Unsaturated Soils,
W84-01755 2D

SOIL SURFACE
Effect of Transient, Partial-Area Shading on Evaporation from a Bare Soil,
W84-01600 2D

SOIL TEXTURE
Groundwater Recharge Through A Heavy-Textured Soil,
W84-01691 2F

SOIL WATER
Extraction and Chemical Analysis of Interstitial Water from Soils and Rocks,
W84-01505 2G

Estimating Soil Moisture Storage in the Root Zone from Surface Measurements,
W84-01598 2G

The Influence of the Initial Water Content on the Redistribution of Soil Water after Infiltration,
W84-01599 5G

Groundwater Recharge Through A Heavy-Textured Soil,
W84-01691 2F

Geostatistical Approach to the Trickle Irrigation Design in Heterogeneous Soil: 1. Theory,
W84-01706 2G

Modeling Tritium and Chloride 36 Transport Through an Aggregated Oxisol,
W84-01711 2G

Estimating Spatial Variability in Soil Moisture with a Simplified Dynamic Model,
W84-01717 2G

SOIL-WATER-PLANT RELATIONSHIPS
Simulation Model of the Water Balance of a Cropped Soil: SWATRE,
W84-01694 2G

SOIL WATER SUCTION
Repetitive-Load Behavior of Unsaturated Soils,
W84-01755 2D

SOLAR RADIATION
Solar Radiation Effects on Frost Action in Soils,
W84-01756 8D

SOLID WASTES
Odour Control in Solid Waste Management,
W84-01564 5D

SOLUTE TRANSPORT
Competitive Adsorption During Solute Transport in Soils: 1. Mathematical Models,
W84-01596 2G

An Integrated Approach to Hydrogeologic Investigations - A Case History,
W84-01692 2F

Gamma Neutron Method Applied to Field Measurement of Hydrodynamic Dispersion,
W84-01697 2G

Modeling Tritium and Chloride 36 Transport Through an Aggregated Oxisol,
W84-01711 2G

Simulation of Solute Transport in a Mountain Pool-and-Riffle Stream: A Transient Storage Model,
W84-01714 2E

Simulation of Solute Transport in a Mountain Pool-and-Riffle Stream with a Kinetic Mass Transfer Model for Sorption,
W84-01716 2K

Identifying Sources of Groundwater Pollution: An Optimization Approach,
W84-01721 5B

Efficient Finite Element Technique for Modeling Transport in Fractured Porous Media; 1. Single Species Transport,
W84-01726 2F

SORPTION
Kinetic Analysis of Strontium and Potassium Sorption onto Sands and Gravels in a Natural Channel,
W84-01715 2K

Simulation of Solute Transport in a Mountain Pool-and-Riffle Stream with a Kinetic Mass Transfer Model for Sorption,
W84-01716 2K

SOUTH AFRICA
Dissolved Ions, Stable and Radioactive Isotopes and Noble Gases in Thermal Waters of South Africa,
W84-01696 2J

SPATIAL DISTRIBUTION
Spatial Distribution Patterns of Planktonic Fish Eggs in Lower Mobile Bay, Alabama,
W84-01405 2L

SPATIAL VARIABILITY
Estimating Spatial Variability in Soil Moisture with a Simplified Dynamic Model,
W84-01717 2G

SPAWNING
Spawning and Early-Life Ecological Phases of the White Sucker in Jack Lake, Ontario,
W84-01410 2H

Identification of Catostomid Larvae in Pyramid Lake and the Truckee River, Nevada,
W84-01411 2H

Microhabitats Chosen by Brown Trout for Feeding and Spawning in Rivers,
W84-01412 2H

SPECIATION
Speciation (Including Adsorbed Species) of Copper, Lead, Nickel and Zinc in the Meuse River; Observed Results Compared to Values Calculated with a Chemical Equilibrium Computer Program,
W84-01680 5B

SPECIES COMPOSITION
Dependence of Biological Treatment Rate on Species Composition in Activated Sludge or Biofilm. I: A Biological Treatment Model with Ecosystem Adaptation,
W84-01516 5D

SPECIES DIVERSITY
Short-Term Standing Crop and Diversity of Periphytic Diatoms in a Eutrophic Reservoir,
W84-01446 5C

SPECTROMETRY
Interferences of Major Elements in the Determination of Lead, Copper, Cadmium, Chromium and Nickel in River Sediments and Sewage Sludges by Electrothermal Atomic Absorption Spectrometry (Interferences des Elements Majeurs sur la Determination de Pb, Cu, Cd, Cr et Ni Dans les Sediments de Cours D'Eau et les Boues de Stations D'Epuration par Spectrometrie D'Absorption Atomique sans Flamme),
W84-01558 5A

SPECTROPHOTOMETRY
Zone Trapping In Flow Injection Analysis; Spectrophotometric Determination of Low Levels of Ammonium Ion In Natural Waters,
W84-01559 5A

Determination of Traces of Polyoxyethylene Non-Ionic Surfactants in Water by Solvent Extraction-Spectrophotometry,
W84-01731 5A

SPILLWAY APRON
Pressures on Spillway Aprons Downstream from Partly Raised Crest Gates,
W84-01487 8B

SPILLWAYS
Pressure Fluctuations on the Bottom of Open-Channel Turbulent Flows in Spillway Structures,
W84-01739 8B

Improvement of the Mechanical Equipment of High-Head Spillways,
W84-01748 8C

Experience in the Design and Construction the Spillway Part of the Zeya Dam,
W84-01752

Small Stream Channel Dam Aeration Characteristics,
W84-01768

SPOIL BANKS
Slaking Modes of Geologic Materials and Th Impact on Embankment Stabilization,
W84-01759

SPRINGS
Hydrogeology of the Littlefield Springs, Ar na,
W84-01553

STABILITY
Evaluation of the Accuracy of Calculating Stability of Slopes of Earth Dams in Ch Calculations of Slopes that Failed,
W84-01740

Scientific Basis of the Designs of the Und ground Structures of the Rogun Hydroelec Station,
W84-01747

STANDARDS
Quality Control in Water Analyses,
W84-01494

STANDING CROPS
Short-Term Standing Crop and Diversity Periphytic Diatoms in a Eutrophic Reserv
W84-01446

STEAM ELECTRIC POWERPLANTS
The Role of Air and Water Residuals for Ste Electric Power Generation,
W84-01605

STEEL
High Tensile Strength Steel for Penstocks,
W84-01614

STILLING BASINS
Internal Flow in Hydraulic Jumps,

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 17, NUMBER 6
JUNE 1984

DEPOSITORY

MAY 16 1984

UNIVERSITY OF ILLINOIS

4-01770 – W84-02124
DDEN: SWRABW

LIBRARY U. OF I. URBANA-CHAMPAIGN

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 6
JUNE 1984

W84-01770 -- W84-02124

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

LIBRARY OF THE UNIVERSITY OF ILLINOIS

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

ATISTICAL ESTIMATION OF POLYNOMI- GENERALIZED COVARIANCE FUNC- ONS AND HYDROLOGIC APPLICATIONS,
va Univ., Iowa City. Inst. of Hydraulic Re-rch.
K. Kitanidis.
ter Resources Research, Vol. 19, No. 4, p 909-, August, 1983. 3 Fig, 32 Ref. NSF grant CME-6577.

scriptors: *Statistical methods, *Hydrology, ovariance, Variance, Rainfall, Error analysis, del studies, Network design.

ree methods for the estimation of the parameters he polynomial generalized covariance function useful model for nonstationary functions) are sented and evaluated: maximum likelihood L), minimum variance unbiased quadratic VUQ), and minimum norm (least squares). The mation error covariance matrix of the param-s is calculated with each of these methods. ML MVUQ estimation have very good properties , for reasonably large samples, give very similar lts. Minimum norm estimation is appropriate preliminary data analysis. The application of e methodologies is illustrated with a set of fall data. The estimation of the parameters of covariance function involves sizeable errors. In ctice, it may be rather difficult to identify the ameters of all but simple models. The proposed ameter estimation methods can be very useful in luating and accounting for the effect of parame-uncertainty in the design of hydrologic data ection networks. (Moore-IVI)

THEMATICAL SIMULATION OF INTER- PENDENT SURFACE AND SUBSURFACE DROLOGIC PROCESSES,
nce and Education Administration, Fort Col- CO. Agricultural Research.
E. Smith, and R. H. B. Hebbert.
er Resources Research, Vol. 19, No. 4, p 987-, August, 1983. 21 Fig, 23 Ref.

criptors: *Storm seepage, *Slopes, *Infiltra-, Permeability coefficient, Hillslopes, Mathe-ical models, Simulation, Hydrodynamics, Soil er, Perched water, Unsaturated flow, Rainfall-off relationships, Western Australia.

athematical model is introduced which repre-s an attempt to integrate all of the major hy-ogic response mechanisms presently identified ontributing to the hydrology of a simple hills-, by selecting efficient approximations for key ents in hillslope hydrodynamics: infiltration movement in the unsaturated flow zone. The lope is considered to consist of two soil layers the lower soil capable of restricting vertical at the interface to create a perched aquifer subsurface stormflow. The slope of the inter- is arbitrary. A kinematic method for routing turated vertical flow is linked consistently a modern analytically derived infiltration el, which operates when rainfall exceeds sur- saturated hydraulic conductivity Ks. The el is used to demonstrate several of the rela-ships between rainfall flux, soil hydraulic prop-s, hillslope geometry, and runoff characteris- The model is also applied to simulate experi-tal data from a hillslope in Western Australia. ical movement in the perched water table g the hillslope and primarily in the near-stream on is potentially more significant in most hills-s than horizontal flux of the resulting perched fer. Subsurface stormflow recession character-s are probably much more related to the loss ern into the subsoil of spatial variability of eability in the surface soil zone than to a acteristic response function of the aquifer hy-lics. The dynamics of the saturated excess onse and the subsurface stormflow are both ily influenced by conditions such as gradients, r table heights, soil depth, and saturations. Subsoil response delay time is largely controlled by the depth of the unsaturated zone. Multiple peaks may be produced from a relatively uncomplicated hyetograph when the expansion of the saturated excess zone interacts with the changes in the rainfall rate. (Moore-IVI)

CALIBRATION OF SNYDER COEFFICIENTS FOR PENNSYLVANIA,
Pennsylvania State Univ., University Park. Dept. of Civil Engineering.
A. C. Miller, S. N. Kerr, and D. J. Spaeder.
Water Resources Bulletin, Vol. 19, No. 4, p 625-630, August, 1983. 3 Fig, 2 Tab, 14 Ref.

Descriptors: *Surface runoff, *Unit hydrographs, *Pennsylvania, Rainfall-runoff relationships, Regression analysis, Storm runoff, Maps.

Unit hydrograph theory is one of the most widely used techniques to predict surface runoff. The present study is concerned with the Snyder unit hydrograph and the calibration of the Snyder coefficients for Pennsylvania. Twenty-seven study basins were selected, located randomly across the state. With the rainfall and runoff recorded for several events for each basin (more than 500 events were analyzed) unit hydrographs were calculated and the Snyder coefficients determined. A map of the coefficients was drawn to illustrate the variability in the coefficients and two equations using multiple regression theory were developed. The unexplained variability of the coefficients suggests that upper and lower bounds on the peak flow might be placed on storm hydrographs developed for ungaged watersheds. (Author's abstract)

ALTERATION OF OCEANIC CRUST AND GEOLOGIC CYCLING OF CHLORINE AND WATER,
Minnesota Univ., Minneapolis. Dept. of Geology and Geophysics.
E. Ito, D. M. Harris, and A. T. Anderson, Jr.
Geochimica et Cosmochimica Acta, Vol. 47, No. 9, p 1613-1624, September, 1983. 3 Fig, 5 Tab, 116 Ref.

Descriptors: *Water cycle, *Geohydrology, *Chlorides, *Geochemistry, Subduction, Hydrothermal studies, Volcanoes, Water transport, Solute transport, Plate tectonics, Geologic cycling, Oceanic crust, Magma, Ocean bottom.

New estimates of transport rates for H2O and Cl between the mantle and surface reservoirs are reported. The estimates take into consideration alteration of oceanic crust, especially that of plutonic rocks, and possible subduction of sediments. The effect of (hydrothermal) alteration on the Cl budget seems to be negligible, but the effect on the H2O budget is significant. Altered oceanic crust (excluding sediments) contains about 10 times as much H2O as the unaltered crust, and its subduction may result in a net transport of H2O to the upper mantle in subduction zones. However, the rate of expulsion of H2O from the mantle by subduction-zone magmatism is comparable to the amount released by ridge magmatism, and is only about 10% of the amount subducted. Therefore, about 90% of the subducted H2O must be returned to the mantle or returned to the crust by other processes. In addition, subduction of oceanic sediments to mantle depths will result in a further increase in the return rate of H2O to the mantle reservoir, and possible net transfer of Cl to the mantle, depending on the rate of pore water expulsion. The reflux of subducted H2O to the surface reservoirs is not fully accounted for by igneous activity at volcanic arcs in subduction zones, or mantle H2O associated with igneous acitvity at oceanic spreading centers and hotspots. (Moore-IVI)
W84-01986

THROUGHFALL AND STEMFLOW IN THE FOREST NUTRIENT CYCLE,
G. G. Parker.
Advances in Ecological Research, Vol. 13, 1983. 14 Fig, 5 Tab, 280 Ref.

Descriptors: *Cycling nutrients, *Precipitation, *Throughfall, *Stemflow, *Forests, Minerals, Forest soils, Leaching, Dry deposition, Washoff.

The quality of precipitation falling on forests is altered during a brief but significant interaction with the surfaces of plants, resulting in the transfer of additional mineral matter to the forest floor. While incident precipitation is the largest nutrient input to many forests, throughfall fluxes are substantially greater, ranging from 1.27 (for NO3-N) to 11.2 times as high (for K). These alterations in nutrient concentrations involve numerous processes and combine materials originating both within (biotic) and outside of the forest ecosystem (atmospheric). The resulting flux is a pathway of rapid mineral cycling, a route for transferring metabolic biproducts and substances of allelochemic and pedogenic importance and a method for washing the air filtering surfaces of the forest canopy. Throughfall and stemflow are major pathways in nutrient recycling. The annual nutrient return to the forest soil for the elements K, Na and S is predominantly via throughfall and stemflow and little due to litterfall. Stemflow transfers only 5-20% of the total in precipitation-borne solutes, yet it is the major nutrient input to restricted areas of the forest floor. Incident precipitation is an underestimate of input and net forest water is an overestimate of canopy-mediated recycling. Without estimates of dry deposition and subsequent washoff, nutrient cycles are unbalanced and atmospheric losses poorly quantified. Throughfall and stemflow show much variability in concentration and deposition, far more than for incident precipitation. Sampling and analyses of forest waters present special chemical and statistical problems. For nutrient budgets, a major difficulty lies in obtaining an accurate and independent estimate of the forest hydrologic budget. For the majority of elements, leaching is the major contribution in net throughfall. (Moore-IVI)

MODEL STUDY OF THE SHORT-TERM CLIMATIC AND HYDROLOGIC EFFECTS OF SUDDEN SNOW-COVER REMOVAL,
National Oceanic and Atmospheric Administration, Princeton, NJ. Geophysical Fluid Dynamics Lab.
T.-C. Yeh, R. T. Wetherald, and S. Manabe.
Monthly Weather Review, Vol. 111, No. 5, p 1013-1024, May, 1983. 16 Fig, 13 Ref.

Descriptors: *Snow cover, *Soil water, *Climate, Albedo, Mathematical models, Simulation, Evaporation, Soil temperature, Air temperature, Insolation, Atmospheric circulation.

This paper describes the results from a set of numerical experiments which simulate the effect of a large scale removal of snow cover in middle and high latitudes during the early spring season. This is done through use of a simplified general circulation model with a limited computational domain and idealized geography. It is found that removal of snow cover reduces the water available to the soil through snowmelt and decreases soil moisture in this region during the following seasons. Furthermore, it also reduces surface albedo in this region and increases adsorption of insolation by the ground surface. This, in turn, heats the ground surface and allows more evaporation to occur. However, the change of evaporation is relatively small owing to the low values of surface temperature in high latitudes. Therefore, the negative anomaly of soil moisture induced initially by the removal of snow cover persists for the entire spring and summer seasons. The removal of snow cover also affects the thermal and dynamical structure of the atmosphere. It is found that the increase of surface temperature extends into the upper troposphere thereby reducing both meridional temperature gradient and zonal wind in high latitudes. (Author's abstract)

2B. Precipitation

A MILLIMETER-WAVELENGTH DUAL-POLARIZATION DOPPLER RADAR FOR CLOUD AND PRECIPITATION STUDIES,
National Oceanic and Atmospheric Administration, Boulder, CO. Wave Propagation Lab.
F. Pasqualucci, B. W. Bartram, R. A. Kropfle, and W. R. Moninger.
Journal of Climate and Applied Meteorology, Vol. 22, No. 5, p 758-765, May, 1983. 7 Fig, 1 Tab, 17 Ref.

Descriptors: *Precipitation, *Radar, Climate Storms, Clouds, Meteorological data collection, Micrometeorology, Montana.

A pulse Doppler radar system operating at 35 GHz and having full polarization (linear and circular) diversity capability is described. Separate antennas are used for the transmitter and the receiver because this design approach allows better overall radar sensitivity. The transmitter operates in the double-pulse mode to optimize the unambiguous Doppler velocity measurable with the system. A polarizer capable of handling about 200 kW of peak power when pressurized with sulfur hexafluoride at 25 psi was developed for the transmitter. The radar system has built-in test sequences for checking the gain and alignment of the transmitter and receiver antennas. The dual-polarization intermediate frequency receiver has a total of six analog channels. A very flexible data acquisition and processing system has been developed to allow both coherent and incoherent dual-polarization measurements to be performed; the system includes a microprocessor-controlled pulse-pair processor and a minicomputer with associated peripherals. The radar was operated successfully in Montana during the 1981 Cooperative Convective Precipitation Experiment. Preliminary results on the observed variation of the circular depolarization ratio demonstrate the usefulness of this sytem for monitoring the kinematics and microphysics of clouds and precipitation with good space and time resolution. SURVEY OF RADAR RAIN MEASUREMENT TECHNIQUES,
National Severe Storms Lab., Norman, OK.
R. J. Doviak.
Journal of Climate and Applied Meteorology, Vol. 22, No. 5, p 832-849, May, 1983. 10 Fig, 74 Ref.

Descriptors: *Rainfall, *Measuring instruments, Rain gage, Clouds, Storms, Estimating.

Several methods used to estimate rainfall rate R are surveyed. The distribution N(D) of drop sizes is of central importance in determining the reflectivity factor Z, attenuation rate K, and R. With single-parameter measurement techniques either of the remotely sensed parameters Z or K can be used to estimate R when gross assumptions on N(D) can be made. If N(D) can be described by a two-parameter distribution, dual measurement techniques can better estimate R without involving these coarse assumptions. A review is made of three techniques whereby two variables might be measured: 1) dual wavelength in which Z and K are remotely measured, 2) dual polarization in which reflectivity is measured with two orthogonal polarizations, and 3) raingage-radar combinations whereby in situ point measurements of R and radar measurement of Z or R are combined to obtain a better assessment of rain over areas between gages. It was concluded that there is still no satisfactory proven method in use to estimate rain rate or liquid water content accurately when high spatial and temporal resolution is needed. Dual-parameter measurement techniques appear to offer the best solution for rain rate estimation if N(D) is a significant error source and high resolution is reqired. There is need to evaluate the relative importance of error sources other than uncertainty in N(D) (Baker-IVI)

SPECIFICATION OF MONTHLY PRECIPITATION IN THE WESTERN UNITED STATES FROM MONTHLY MEAN CIRCULATION,
California Univ., Davis. Dept. of Land, Air and Water Resources.
B. C. Weare, and M. A. Hoeschele.
Journal of Climate and Applied Meteorology, Vol. 22, No. 6, p 1000-1007, June, 1983. 8 Fig, 2 Tab, 16 Ref.

Descriptors: *Rainfall, *Weather forecasting, Spatial distribution, Forecasting, California, Oregon, Washington.

The ability to specify monthly precipitation at 36 stations in Washington, Oregon and California by various indices of monthly mean circulation has been investigated. Most of the circulation indices were derived from eigenvector analyses of 700 mb geopotential heights or relative vorticity for 1951-76 or 300 mb relative vorticity for 1963-76. The results indicate that an average up to 60% of the rainfall variance may be specified by same-month average circulation parameters. The 700 mb parameters analyzed within a limited domain in the vicinity of the rainfall network result in the best specification ability. Indices derived from larger domains or from the 300 mb vorticities result in generally poorer specifications. Considerable spatial variation in specification ability is apparent with greatest skills evident in the coastal region of northern California and Oregon and lowest skills in the eastern regions of all three states. HEAVY THUNDERSTORMS OBSERVED OVER LAND BY THE NIMBUS 7 SCANNING MULTICHANNEL MICROWAVE RADIOMETER,
Wisconsin Univ.-Madison. Space Science and Engineering Center.
R. W. Spencer, W. S. Olson, W. Rongzhang, D. W. Martin, and J. A. Weinman.
Journal of Climate and Applied Meteorology, Vol. 22, No. 6, p 1041-1046, June, 1983. 9 Fig, 23 Ref.

Descriptors: *Thunderstorms, *Satellite technology, *Weather forecasting, Rain, Radiometry, Clouds, Climate, Temperature effects.

In an examination of microwave data from the Nimbus 7 satellite, brightness temperatures were found that were much lower than those expected for the radiation emanating from rain-producing clouds. Even over land brightness temperatures much colder than those predicted from rain layer models occasionally are observed and in every case of cold brightness temperature heavy rain was observed at the surface. The cold temperatures can be explained if there is a thick layer of precipitation-sized ice hydrometeors above the rain. The same structure, presumably a wide, strong updraft, that allows a storm to carry precipitation well above the freezing level apparently also favors heavy rain. Thus it appears that the 37 GHz observations do at times contain information on relatively heavy rain rates. The coincidence of the coldest brightness temperatures with the most extreme weather events suggests as well that the 37 GHz channel may have some value in detecting severe local storms. (Baker-IVI)

PRECIPITATION IN SOUTHERN NEVADA,
Nevada Univ. System, Las Vegas. Water Resources Center.
R. H. French.
Journal of Hydraulic Engineering, Vol. 109, No. 7, July, 1983. 6 Fig, 8 Tab, 8 Ref. DOE contract DE-AC08-DPO-1253.

Descriptors: *Precipitation, *Nevada, Spatial distribution, Temporal distribution, Groundwater recharge, Flash floods.

The distribution of precipitation in both time and space in the southern Nevada area is examined. It is concluded that this area can be divided into two zones of precipitation separated by a transition zone on the basis of annual average precipitation. One region, relative to the other area, is define be a deficit annual average precipitation reg This observation could have a significant im on groundwater recharge estimates and on siting of facilities which must be protected f flash floods. In addition precipitation record two stations in the southern Nevada area v examined and point intensity/duration relat ships were derived for these stations. (Auth abstract)

LARGE FALLS OF RAIN IN WALES - SIMPLE STATISTICAL CASE STUDY,
I. T. Jolliffe.
Weather, Vol. 38, No. 4, p 103-106, April, 198 Tab, 1 Ref.

Descriptors: *Rainfall, *Statistical analysis, *F quency, Storms, Wales, Beacons Reservoir, Sw sea.

The possibility that an apparent increase in frequency of large rainfalls from the period 19 1980 as compared to the period prior to 1925 Wales may be due strictly to chance is investig ed. Three well known probability distributions nomial, Poisson, exponential) are used to determ the validity of this theory. The three techniq come to somewhat similar conclusions. For B cons Reservoir there is strong evidence that frequency of falls of rain of at least 2 or 3 in higher for the later parts of the data. The evide is less convincing for higher rainfalls (4 and 5 but this may be partly due to the small amounts data which are available. For Swansea, there is convincing evidence that the frequency of la rainfalls has changed during the period of obser tion. (Baker-IVI)

CIRCULATION TYPE AND THE SPATI DISTRIBUTION OF PRECIPITATION OV CENTRAL, EASTERN AND SOUTHERN EN LAND: PART II,
J. Stone.
Weather, Vol. 38, No. 7, p 200-205, July, 1983 Fig, 17 Ref.

Descriptors: *Weather patterns, *Precipitati *Atmospheric circulation, Spatial distributi England, Rainfall distribution.

A study was made of maps showing the mean da precipitation for the period 1961 to 1975 with t various cyclonic directional (or hybrid) types the Lamb catalogue. Indications were clear th the spatial variation of the mean daily precipitati varied a great deal with different circulation typ Proximity to low pressure, the curvature of t isobars and frontal activity are all important fa tors which help to explain these variations. Oth factors include the uplift afforded by relatively lo hills, sometimes no more than 50 meters high, a relative exposure to or shelter from moist win from the sea. Uplift and exposure are especial important when they operate in combination. Th can be seen in sourthern counties with both t straight isobar and cyclonic southerly and sout westerly types. On these occasions significant more precipitation fell inland over the low hi away from the coastal lowlands. This form intensification of precipitation also occurs in No folk when moist air streams blow inland off th North Sea. At the same time, however, ma southern and south-western areas are sheltered a receive less precipitation than Norfolk. Antic clonic types generally give light intensities. Certa areas received high daily precipitation from rel tively few circulation types. East Anglia for exa ple, received large falls mainly from the cyclon cyclonic north-westerly, straight isobar norther and cyclonic northerly types. (Baker-IVI)

RAINSHADOW - THE DYNAMICAL FACTO
Queen Mary Coll., London (England).
B. W. Atkinson.

ather, Vol. 38, No. 9, p 264-269, September, 3. 4 Fig, 9 Ref.

scriptors: *Rainfall distribution, *Weather pat-ns, *Rainshadow, Precipitation, England, les.

tribution of precipitation over a given area in a time is largely a function of the interplay ween airflow, cloud physics and topography. If effects of uniform frontal uplift and orography combined, one would expect a large precipita- area associated with the front within which vier precipitation would occur over hills. Con-sely, when presented with a precipitation map wing strong localization of precipitation over nd areas, it would be easy to conclude, though aps wrongly, that only orographical influences been operating. In considering such a case it omes clear that precipitation which occurred 29 July 1967 over England and Wales resulted n a combination of dynamical, orographical cloud-physical factors. As the frontal rain s moved north-eastward, a striking rainshadow ct appeared. This lack of precipitation to the of the Welsh hills was due largely to the amical factor rather than the orographical and d-physical factors. The case is an interesting inder that rainshadows are not always what seem to be. (Baker-IVI)

GNOSTIC STUDIES OF RAINFALL OMALIES IN NORTHEAST BRAZIL,
consin Univ.-Madison. Dept. of Meteorology.
Chu.
thly Weather Review, Vol. 111, No. 8, p 1655-, August, 1983. 12 Fig, 18 Ref.

criptors: *Rainfall, *Brazil, *Atmospheric cir-tion, Drought, Departure patterns, Rainy on, Dry season, Weather, Sea surface tempera-

large-scale atmospheric circulation of the il-Atlantic sector is studied in relation to ex-e rainfall anomalies in two large regions of heast Brazil (Nordeste). Long-term rainfall s, aerological records of stations in South rica, and ship observations over the tropical ntic form the data base for this study. Depar- patterns of meteorological elements over the ntic are investigated for composites of ex-ely dry and wet years in the southern and ern Nordeste. Southern Nordeste's peak rainy on is around November/December. The wet s in the southern Nordeste are marked by tive pressure departures over the South Atlan-veak onshore southeast trades and anomalous-ld waters along the south Brazil coast. These res appear to be related to Southern Hemi-ric frontal systems. During the dry years, de-re patterns are nearly reversed to those of the years. Northern Nordeste receives its maxi- rainfull in March/April. Rainfall variations nodulated by the latitudinal displacement of baric trough and confluence axis over the torial Atlantic and concomitant sea surface erature anomalies. Case studies of recent ex-e years indicate the possible existence of a meridional circulation. The more northerly ion of the convergence band over the Atlan-he anomalously cold waters to the south of the tor and the subsidence in the southern portion he thermally-induced meridional circulation over the Nordeste, characteristics of drought , are all unfavorable for rainfall in Northeast l. -SAHARAN RAINFALL IN THE YEARS -80: EVIDENCE OF CONTINUED OUGHT,
Univ., Worcester, MA. Graduate School of graphy.
Nicholson.
thly Weather Review, Vol. 111, No. 8, p 1646-August, 1983. 7 Fig, 1 Tab, 20 Ref. NSF ATM-80-19009.

riptors: *Drought, *Rainfall, *Sub-saharan a, Africa, Biogeophysical feedback.

Rainfall is represented by a standarized annual departure calculated as the ratio of the annual departure to the standard departure. The departures for each of the five years are calculated for four semi-arid sub-Saharan zones (Sahelo-Sahara, Sahel, Soudan, Soudano-Guinean) and compared with values for the period 1901-75. Departures for regional subdivisions and individual stations are also derived. The analysis clearly shows that drought persisted in the region until at least 1980. Rainfall was well below normal in all four zones in 1976 and 1977. In most areas, deficits for these years were comparable to those of 1972 and 1973, the years of most extreme drought. Rainfall was below average in all years in nearly every region and for nearly every station. The persistence of extreme rainfall deficits throughout the 1970's may be a result of a biogeophysical feedback mechanism which promotes intense and persistent droughts. (Moore-IVI)

LINEAR ORGANIZATION OF LOCALIZED STORMS IN THE SUMMER RAINFALL ZONE OF SOUTH AFRICA,
Hebrew Univ., Jerusalem (Israel). Inst. of Earth Sciences.
D. Sharon.
Monthly Weather Review, Vol. 111, No. 3, p 529-538, March, 1983. 10 Fig, 4 Tab, 13 Ref.

Descriptors: *Rainstorms, *South Africa, Spatial distribution, Rainfall distribution, Drought, Seasonal variation.

The spatial organization of localized showers in the summer rainfall region of South Africa has been studied by means of spatial correlation functions. A predominant linear arrangement of parallel shower belts has been identified, with an orientation between W-E and WNW-ESE. No differences were found in this respect between the driest years in the 1960's and the wettest ones in the 1950's and 1970's, but a linear trend was absent, or at least not prevalent at any fixed orientation, during the dry spell extending from the late 1940's to the early 1950's. The above linear trend has been found to persist also throughout the year, though, in general, rainfall appeared as spatially less organized during summer months than during spring and autumn. RELATIONSHIP BETWEEN EASTERN EQUATORIAL PACIFIC SEA SURFACE TEMPERATURES AND RAINFALL OVER INDIA AND SRI LANKA,
National Weather Service, Washington, DC. Climate Analysis Center.
E. M. Rasmusson, and T. H. Carpenter.
Monthly Weather Review, Vol. 111, No. 3, p 517-528, March, 1983. 9 Fig, 6 Tab, 28 Ref.

Descriptors: *Rainfall, *Sea surface temperature, *India, *Sri Lanka, El Nino, Monsoons, Forecasting.

Monsoon season (June-September) precipitation data from 31 Indian subdivisions and mean monthly precipitation data from 35 Indian and Sri Lanka stations, spanning the period 1875-79, were analyzed to determine the relationship between equatorial Pacific warm episodes (El Nino events) and interannual fluctuations in precipitations over India and Sri Lanka. The data reveal a strong tendency for a below normal summer monsoon during the 25 moderate/strong warm episodes which occurred during the period. For example, area-averaged June-September rainfall over India was below the median value in 21 of the 25 warm episode years. These years include the five largest, and nine of the eleven largest, negative monsoon season anomalies. Considerably smaller average departures occurred during the monsoon seasons of the year preceding and the year following the warm episode, and during the remaining months of the warm episode year. The anomaly pattern over Sri Lanka and extreme southern India is quite different, the major feature being a period of above normal precipitation during the autumn of the warm episode year. During a typical warm episode, positive sea surface temperature anomalies appear along the Ecuador Peru coast early in the year, and thus precede the summer monsoon by several months. The forecasting implications of this relationship are discussed. (Author's abstract)

ONSET OF THE AUSTRALIAN MONSOON DURING WINTER MONEX: SYNOPTIC ASPECTS,
Australian Numerical Meteorology Research Centre, Melbourne.
N. E. Davidson, J. L. McBride, and B. J. McAvaney.
Monthly Weather Review, Vol. 111, No. 3, p 496-516, March, 1983. 10 Fig, 1 Tab, 23 Ref.

Descriptors: *Monsoons, *Australia, *Weather, Troposphere, Clouds, Satellite technology, Southern Hemisphere.

A case study is presented of the onset of the Southern Hemisphere summer monsoon at longitudes near Australia during December 1978. The numerical analyses comprising this case study are used in conjunction with station data and operational manually derived analyses for other years to investigate the following: 1) the ease of definition of monsoon onset; 2) the three-dimensional structure of the troposphere during an active monsoon situation; and 3) the flow changes preceding and during the transition from a period of suppressed to a period of enhanced cumulonimbus activity over tropical Australia. A well-defined onset occurs in six of the seven years considered. Onset, defined as a satellite-observed, large-scale increase in tropical convection, is consistent with that determined by the wind criterion of Troup (Indian J. Meteor. Geophys., 1961, 12, 217-230). In 1978 onset occurs in two stages: an increase in convergence, followed by an increase in convection. The monsoon cloudiness exists entirely in the region of low-level westerly wind. The convergence extends through a deep layer from the surface at 400 mb and exists in the upward branch of two linked Hadley cells, one from each of the Northern and Southern Hemispheres. Observations of the flow changes prior to onset lead to the hypothesis that the trigger mechanism lies in the Southern Hemisphere subtropics. It is conjectured that the seasonal buildup of planetary-scale land-sea temperature gradients has reached a critical stage such that the troposhere is in a state of readiness for the monsoon. Before the onset can take place, however, it must wait for the Southern Hemisphere midlatitude synoptic systems to be in such a configuration that low-level trade wind easterlies are prevalent across the Australian continent. The evidence is discussed also in favor of various alternative triggering mechanisms such as the influence of a Northern Hemisphere cold surge in the South China Sea and the westward propagation of equatorial westerlies from the Pacific Ocean near the international date line. PHYSICAL BASIS FOR CHANGES IN THE PHASES OF THE SUMMER MONSOON OVER INDIA,
World Meteorological Organization, Baghdad (Iraq). Regional Training Center.
P. S. Pant.
Monthly Weather Review, Vol. 111, No. 3, p 487-495, March, 1983. 5 Fig, 1 Tab, 20 Ref.

Descriptors: *Monsoons, *Rainfall, *India, Weather, Meridional circulation, Mathematical models, Tibetan plateau, Eddy heat flux.

The summer monsoon over India is described as 'active' when large parts of India, particularly the central parts and the west coast receive normal or above normal rainfall. It is described as having a 'break' when the rainfall is below normal over most parts of India, except in the hills in the north and in the southeastern parts of the country. It is shown in this paper that when a break sets in, there is an in-situ formation of a zonally oriented trough at 10-15 degrees N at 700 mb over south India and

the adjoining seas. Simultaneously, there is a sharp fall in the 500 mb temperature over the Tibetan Plateau to much below normal values. As the plateau warms and attains near normal temperature, the trough in the south shifts northward and occupies the normal active monsoon trough position (around 20 degrees N) over north India. Considering the importance of meridional circulations in the tropics, it is reasonable to expect that the changes in the 700 mb flow with the phase changes are associated with corresponding changes in the meridional circulation. Computations of vertical motion along 75 degrees E with the help of quasi-geostrophic model show that under break monsoon conditions, the Hadley cell with its upward limb in the trough at 10-15 degrees N over south India and descent further north, predominates. Whereas, in the active monsoon phase, the monsoon cell, with a rising limb at about 20 degrees N and descent in the south, is prominent. The physical process through which the sudden cooling over the Tibetan Plateau brings about a change in the meridional circulation, and therefore a change in the phase of the monsoon from an active to a break situation, is explored through a quasi-geostrophic streamfunction for the meridional circulation. It is seen that eddy fluxes, particularly of heat, are one to two orders of magnitude larger at the northern end of the monsoon cell at the time of disruption of the monsoon. The vertical motions induced by these eddy fluxes are seen to be in the right direction to bring about a switch over from the monsoon cell to the Hadley cell. The re-establishment of the monsoon cell and with it the active phase appears to take place slowly through radiational heating over the Tibetan Plateau. (Author's abstract)

2C. Snow, Ice, and Frost

MELTWATER MOVEMENT IN A DEEP SNOWPACK; 1. FIELD OBSERVATIONS,
British Columbia Univ., Vancouver. Dept. of Geography.
P. Jordan.
Water Resources Research, Vol. 19, No. 4, p 971-978, August, 1983. 8 Fig, 22 Ref.

Descriptors: *Snowmelt, *Snowpack, *Flow, Unsaturated flow, Darcy's law, Conductivity, Capillary pressure, Hydrologic budget, Energy, Wave front, Hydraulic properites, Water content.

The flow of meltwater through a snowpack can be described by Darcy's law, and by a set of equations relating conductivity, capillary pressure, and liquid water content which are similar to the equations governing unsaturated groundwater flow. Field observations were conducted which were designed to test the applicability of the unsaturated flow equations to the description of meltwater movement at the scale of a small watershed. Simple instrumentation was used to measure capillary pressure and meltwater flux rates; this was supplemented with energy and water balance measurements for the study watershed. Observations of surface snowmelt, meltwater flux, and streamflow for the snowmelt period confirm the nature of meltwater flow as described by the unsaturated flow equations, and illustrate the controlling influence of snowpack hydraulics on the streamflow hydrograph. Observed speeds of the meltwater wave front in the snowpack average about 0.22 m/h, and capillary pressures and kinematic wave speeds observed are comparable to those reported in other deep-snow environments. The difficulty of obtaining reliable liquid water content measurements is identified as a major limitation in the determination of hydraulic properties of the snowpack. (Author's abstract)

MELTWATER MOVEMENT IN A DEEP SNOWPACK; 2. SIMULATION MODEL,
British Columbia Univ., Vancouver. Dept. of Geography.
P. Jordan.
Water Resources Research, Vol. 19, No. 4, p 979-985, August, 1983. 3 Fig, 1 Tab, 8 Ref.

Descriptors: *Snowmelt, *Snowpack, *Flow, Unsaturated flow, Mathematical models, Simulation, Energy, Hydraulic properties, Permeability coefficient, Conductivity, Capillary pressure, Water content.

A numerical simulation model is developed describing the one-dimensional flow of meltwater in a snowpack, based on established methods of modeling unsaturated groundwater flow. The results of field observations of snowmelt and meltwater flow are used to determine parameters describing the hydraulic properties of the snowpack, and surface energy balance measurements are used as input to the model. Tests of the performance of the model show a high sensitivity to the saturated hydraulic conductivity of the snowpack and to liquid water content of the snow. Saturated hydraulic conductivity can be measured with acceptable precision by simple field methods; however, measurement of liquid water content is more difficult and constitutes the major limitation affecting calibration of the model. The model is relatively insensitive to exponents in the power law equations relating conductivity, capillary pressure, and liquid water content. Meltwater wave speeds predicted by the model are somewhat slower than those observed in the field. Observations of snowpack layering and horizontal inhomogeneity of flow suggest that these features affect transient storage of meltwater and consequently cause meltwater wave speeds to differ from those predicted by a one-dimensional model. HYDROMETEOROLOGICAL SIGNIFICANCE OF RIME ICE DEPOSITS IN THE COLORADO ROCKIES,
Colorado State Univ., Fort Collins. Dept. of Atmospheric Science.
E. E. Hindman, R. D. Borys, and P. J. DeMott.
Water Resources Bulletin, Vol. 19, No. 4, p 619-624, August, 1983. 3 Fig, 1 Tab, 24 Ref. NSF grant ATM 8109590.

Descriptors: *Rime ice, *Snowpack, *Mountains, Water content, Clouds, Snow, Rocky Mountains, Steamboat Springs, Colorado.

Observations and measurements were made during storm periods at mountain top sites in the Colorado Rockies during the winter of 1981-1982. On average, liquid clouds occurred with and without snowfall for, respectively, 75% and 15% of the observations. On average, the rime ice deposition rates were measured to be seven times the precipitation rates. The rime deposits were estimated to contribute 10% to the water content of the snowpack. Combining this figure with the estimated rime deposits on falling snow crystals (up to 50% by mass), up to 60% of the water content of the annual snowpack in the mountains near Steamboat Springs, Colorado, could be due to rime ice deposits. 2D. Evaporation and Transpiration

FREE AND FORCED CONVECTION EFFECT ON EVAPORATION,
Clemson Univ., SC. Dept. of Mathematics.
B. L. Sill.
Journal of Hydraulic Engineering, Vol. 109, No. 9, p 1216-1231, September, 1983. 7 Fig, 3 Tab, 18 Ref.

Descriptors: *Evaporation, *Surface water, Mathematical studies, Convection, Wind, Temperature effects, Mathematical equations.

The effects of free and forced convection mechanisms on evaporation from open water bodies is examined. Analogies between momentum, heat, and mass transfer from flat surfaces are employed to develop expressions for free and forced convective mass transport (evaporation). Use of these expressions with existing data sets from seven water bodies allows evaluation of the efficiencies of the two convection mechanisms. For the range of conditions studied here, forced convective transfer occurs at its theoretically predicted (or 100% efficient). However, the presence wind tends to disrupt free convective tra with the result that this mechanism becomes fective at high wind speeds or low values o face to air temperature difference. A new fo the Dalton type evaporation equation is also sented which is applicable over a wide ran conditions. (Baker-IVI)

FLOW IN ALLUVIAL-RIVER CURVES,
Universidad Central de Venezuela, Caracas. Fac tad de Ingenieria.
M. F. Ascanio, and J. F. Kennedy.
Journal of Fluid Mechanics, Vol. 133, p 1- August, 1983. 8 Fig, 15 Ref.

Descriptors: *Fluid mechanics, *Channels, *Al vial rivers, Rivers, Shear stress, Fluctuations.

Uniform flow in curved, wide, erodible-bed ch nels is formulated on the basis of the conservat of flux of moment-of-momentum, to obtain re tions for the vertical distributions of radial-pla velocity and radial shear stress. The expression the radial stress exerted on the bed is utilized i force-equilibrium analysis of the moving bed la to obtain relations for the average transverse slo of the bed and for the radial bed profile. T reduction of primary bed shear stress due to net radial transport of streamwise momentu toward the outer (concave) bank is then calculate by introducing the derived expressions for t velocity components into the momentum equati for the primary-flow direction. It is found that t stress reductions in deep, narrow channels c exceed 50%. Bed profiles and velocity distrib tions measured in natural and laboratory strea are found to be in good conformity with tho calculated from this moment-bases theory. (A thor's abstract)

JDAS computer model was used to simulate
f over a catchment within the city of Montre-
anada. A ten-year period, five-minute incre-
rainfall data base was used to derive peak
frequency curves. Two types of design storms
analyzed: one derived from intensity duration
ency curves (Chicago type), the other from
ging actual rainfall patterns (Huff type). An-
ent soil moisture conditions were considered
e analyses. It was found that the probability
bution of runoff peak flow was sensitive to
hoice of design storm pattern and to the
edent soil moisture condition. A symmetrical,
go-type design storm with antecedent dry
noisture produced a flow frequency curve
r to the one obtained from a series of histori-
infall events. (Author's abstract)

nlinear functional rainfall-runoff model is ap-
to an urban watershed (Curotte-Papineau,
real) and the results are compared with those
the ILLUDAS model. Simulations are per-
d using a 5 minute time interval in order to
define the characteristics of the hydro-
s. Particular emphasis is placed on the identi-
on of the most appropriate set of model pa-
ers, namely the memory of the catchment (U)
he order of expansion of the first-order and
d-order kernels M1 and M2. Parameter iden-
ion based on calibration results alone can
o unpredictable verification (prediction) re-
while calibration results improve with in-
ng values of M1 and M2, verification results
t exhibit the same consistency. Consequently,
-way calibration-verification analysis is rec-
ended for obtaining the best set of model
eters. Further, results of the nonlinear func-
runoff model compare favorably with those
ILLUDAS model. (Author's abstract)

REALISTIC ASSESSMENT OF MAXIMUM FLOOD POTENTIALS,
D. W. Newton.
Journal of Hydraulic Engingeering, Vol. 109, No. 6, p 905-918, June, 1983. 6 Fig, 13 Ref.

Descriptors: *Probable maximum flood, *Probability, *Dam design, Dam evaluation, Design floods, Rainfall distribution, Storms, Headwaters, Flood hydrographs, Climate, Tennessee Valley.

A procedure is proposed which uses probability concepts to achieve a consistent realistic assessment of the probable maximum flood (PMF) and its use in design or evaluation of high-hazard dams. A PMF computation involves selection of a sequence of meteorologic and hydrologic events. These include the principal storm, antecedent and/or subsequent storms, time and areal distribution of rainfall, loss rates, and the hydrograph determination. Computed maximum headwater levels used in dam design or evaluation depend on assumed initial reservoir levels, operating conditions, and windwave conditions. A review of present practice shows basic agreement on events or conditions to postulate, but signficant differences in their magnitude. These differences produce major variations in the relative magnitude of computed flood. Further, some events are defined in terms which, when applied in different climatic regions, will result in computed floods of varying relative magnitude. The results of studies conducted by Tennessee Valley Authority to establish a consistent and realistic standard for PMF determination in the Tennessee Valley region are used to illustrate the proposed procedures. A RESIDUAL NOISE MODEL FOR STREAMFLOW PREDICTION,
Ontario Ministry of the Environment, Toronto. Water Resources Branch.
L. A. Logan, W. C. Lennox, and T. E. Unny.
Canadian Journal of Civil Engineering, Vol. 10, No. 3, p 437-449, 1983. 7 Fig, 1 Tab, 15 Ref.

Descriptors: *Streamflow, *Prediction, Forecasting, Model studies, Residual noise, Hydrologic models.

A nonlinear, conceptual hydrologic model is formulated for use in predicting flows under conditions of controlled input. The model has time invariant parameters and a residual noise model is incorporated for sequential prediction of hourly flows using a closed loop feedback scheme with hypothetically controlled inputs which are adapted to the residuals. The residual model derived comprises error terms which are correlated in time and variable. This implication was resolved from the fact that more effective improvement in prediction was attained in cases where the hydrologic model residual autocorrelations appear to be correlated. The suitability of the model to predict flows at different times at a site involving data not included as part of the calibration and with suboptimal basic model parameters is demonstrated. This residual noise and adapted input control adjustment approach will be useful in simple test applications for contingency plans on control of reservoir releases during storm events, or as a means of providing a measure for flood mitigation at damage centers. DYNAMIC MODEL FOR THE OVERLAND FLOW ON AN INFILTRATING CATCHMENT,
Helsinki Univ. of Technology, Espoo (Finland). Systems Theory Lab.
K. Pingoud.
Applied Mathematical Modelling, Vol. 7, No. 2, p 128-134, April, 1983. 7 Fig, 21 Ref.

Descriptors: *Surface runoff, *Overland flow, *Infiltration, Mathematical models, Rainfall-runoff relationships, Catchment areas, Simulation.

An approximate lumped parameter model for the surface runoff phenomenon on a catchment is presented. It consists of two submodels which are spatial discretizations of the basic partial differential equations of overland flow and infiltration. The aim of the model is to describe the dynamical input-output relationship between the rainfall rate and the surface runoff from the catchment. The boundary conditions of the infiltration process are modelled in an approximate way so that the number of state variables in the model can be reduced. With the aid of a single model parameter it is possible to describe simple catchment shapes like linearly converging and diverging surfaces. The model structure is flexible so that it can also be applied to more complex catchment configurations. The simulation results show that the phenomenon under consideration can be properly described by the model structure presented. (Moore-IVI)

FLOODS: AUSTRALIA'S AWFUL VISITATIONS,
Bureau of Meteorology, Melbourne (Australia).
J. F. Elliott.
Weatherwise, Vol. 36, No. 3, p 114-117, June, 1983. 2 Fig.

Descriptors: *Floods, *Australia, Flood control, Cyclones, Rainfall, Flood damage, Monsoons, Urban areas, Flood forecasting.

Floods are a major problem in Australia with almost every area of the continent subject to this type of devastation. Floods are particularly severe in their effects when they occur near major population centers and areas of intense agriculture which are often found on lower river valleys and plains. The inland rivers of northern New South Wales drain very productive agricultural areas and a number of provincial cities are sited on their flood plains. The area is subject to frequent flooding and despite various measures taken to mitigate their effects, floods continue to be a problem. Cyclonic and monsoonal rain are the major causes of flooding in the country. Flash floods are also a problem, but not as severe a problem as in the United States. Flood forecasting and warning services, coupled with a range of emergency service and counter disaster activities have been developed to varying degrees in most areas. Land use controls and planning measures are also being adopted. (Baker-IVI)

DETERMINATION OF BULK ROCK PROPERTIES FROM GROUND-WATER LEVEL FLUCTUATIONS,
Texas A and M Univ., College Station. Dept. of Geology.
P. A. Domenico.
Bulletin of the Association of Engineering Geologists, Vol. 20, No. 3, p 283-287, 1983. 1 Tab, 16 Ref.

Descriptors: *Water level fluctuations, *Stress analysis, *Groundwater, Mathematical studies, Stress, Stress-strain curves, Stress analysis, Water level, Water table.

Ideas from stress-strain theory have been redeveloped in order to relate water level fluctuations to the bulk elastic properties of the last rock. The detailed constitutive relations for isothermal porous mediums are briefly restated. The response of ground-water levels to tides and changes in barometric pressure provides an in-situ measure of the response of the rock-water system to changes in stress. Tidal and barometric efficiencies can thus be expressed in terms of drained and undrained moduli. In addition, if the various moduli are known from laboratory measurements, the laboratory equivalents of both tidal and barometric efficiency can provide an estimate of the specific storage. The method is demonstrated to provide reasonable and consistent results when applied to various rock types of differing rigidity including clay, sandstones, limestone and basalt. (Baker-IVI)

IN-SITU DETERMINATION OF SOIL HYDRAULIC PROPERTIES DURING DRAINAGE,
Alabama Agricultural Experiment Station, Auburn.
J. H. Dane, and S. Hruska.
Soil Science Society of America Journal, Vol. 47, No. 4, p 619-623, July-August, 1983. 7 Fig, 19 Ref.

Descriptors: *Soil water, *Permeability coefficient, *Drainage, Boundary conditions, Soil water retention.

In-situ soil water retention and hydraulic conductivity relations were determined for two soils from knowledge of initial and boundary conditions and water content profiles during drainage. Empirical relations were assumed for each soil between volumetric water content (theta) and soil water pressure head (h), and between hydraulic conductivity (K) and theta. Assigning values to the parameters in these relations made it possible to solve the general water flow equation for the same initial and boundary conditions as encountered in the drainage experiments. Calculated water content profiles were compared with measured water content profiles at corresponding times. Differences in measured and calculated theta values provided information for changes to be made in the parameters. This procedure was repeated until a satisfactory agreement was found and the determined relations apparently represented the soils in question. (Author's abstract)

MATHEMATICAL MODEL FOR REGIONAL LAND SUBSIDENCE DUE TO PUMPING; 3. INTEGRATED EQUATIONS FOR A PHREATIC AQUIFER,
Delaware Univ., Newark. Dept. of Civil Engineering.
M. Y. Corapcioglu, and J. Bear.
Water Resources Research, Vol. 19, No. 4, p 895-908, August, 1983. 10 Fig. 16 Ref. Engineering Foundation grant RC-A-79-1A.

Descriptors: *Subsidence, *Pumping, *Drawdown, *Horizontal displacement, Aquifers, Mathematical models, Water table fluctuations, Groundwater surface, Confined aquifers, Stress.

A mathematical model is developed for the areal distribution of drawdown, land subsidence, and horizontal displacements due to groundwater pumping from a deformable phreatic aquifer. Following the development of a three-dimensional mathematical model consisting of a mass conservation equation, quasi-static equilibrium equations, and stress-strain relations for an assumed perfectly elastic solid matrix, a regional, horizontal two-dimensional model is derived by averaging the three-dimensional model over the vertical thickness of the aquifer, taking into account the continuous variation in total stress as a result of water table fluctuations. The separation of an initially coinciding phreatic surface, which serves as the upper boundary of the aquifer, and a surface consisting of a set of solid particles during the lowering of the water table and the compaction of the aquifer has been incorporated into the averaging procedure. The analytical solution for the case of a single pumping well, which is expressed in terms of the classical well function for a confined aquifer but with a modified storativity, provides estimates of drawdown, vertical subsidence, and horizontal displacements. The displacements for a sample problem are compared with those of a confined aquifer under similar conditions. Under the conditions of the studied case of radial flow, vertical and horizontal displacements due to pumping from a phreatic aquifer with the same discharge rate would be less than those of a confined one. The same averaging procedure is extended for a system of phreatic and leaky confined aquifers and for the unsaturated zone above the water table. An additional change in total stress is obtained in terms of moisture content of the zone above the phreatic surface. (Moore-IVI)

LABORATORY INVESTIGATIONS OF STEAM FLOW IN A POROUS MEDIUM,
W. N. Herkelrath, A. F. Moench, and C. F. O'Neil, II.
Water Resources Research, Vol. 19, No. 4, p 931-937, August, 1983. 6 Fig, 1 Tab, 17 Ref, 1 Append.

Descriptors: *Steam flow, *Geothermal studies, *Pressure, Sand, Silt, Clay, Porous media, Adsorption, Simulation, Mathematical models, Radioactive wastes.

Transient, superheated steam flow experiments were run by bringing a cylinder of porous material to a uniform initial pressure and then making a step increase in pressure at one end of the sample while monitoring the pressure transient breakthrough at the other end. At 100 degrees, 125 degrees, and 146 degrees C, the time required for steam pressure transients to propagate through an unconsolidated material containing sand, silt, and clay was 10-25 times longer than predicted by conventional superheated steam flow theory. The delay in the steam pressure transient may be caused by adsorption of steam in the porous sample. In order to account for steam adsorption, a sink term was included in the conservation of mass equation. Energy transfer in the system has to be considered because latent heat is released when steam adsorption occurs, increasing the sample temperature by as much as 10 degrees C. The steam pressure was a function of both the temperature and the amount of adsorption in the sample. This function was assumed to be an equilibrium adsorption isotherm, which was determined by experiment. By solving the modified mass and energy equations numerically, subject to the empirical adsorption isotherm relationship, excellent theoretical simulation of the experiments was achieved. Quantitative understanding of the physics of the flow of steam in porous media is important in modeling fluid transport in geothermal systems and in high-level nuclear waste repositories. (Moore-IVI)

THEORETICAL EXPLANATION OF SOLUTE DISPERSION IN SATURATED POROUS MEDIA AT THE DARCY SCALE,
Indiana Univ. at Bloomington. Dept. of Mathematics.
R. N. Bhattacharya, and V. K. Gupta.
Water Resources Research, Vol. 19, No. 4, p 938-944, August, 1983. 1 Fig, 18 Ref. NSF grants CME-8004498 and CME-8004499.

Descriptors: *Porous media, *Solute transport, *Dispersion, Peclet number, Convection, Probability, Darcy scale.

The transport of a nonreactive dilute solute in saturated porous media is explained at three distinct space-time scales. These are the kinetic, microscopic, and Darcy scales. The transition from one scale to the next higher scale, i.e., from the kinetic to the microscopic to the Darcy, is a consequence of the central limit theorem of probability theory. At the microscopic scale, the solid and the liquid phases together form a heterogeneous continuum. The microscopic solute concentration is governed by a parabolic equation with spatially varying drift and diffusion coefficients. The so-called dispersion phenomenon at the Darcy scale is shown to appear in the transition from the microscopic to the Darcy scale. In the computation of the dispersion coefficients, the Peclet number appears naturally as a dimensionless parameter. For large Peclet numbers the coefficients of dispersion at the Darcy scale are shown to be linear in the liquid convective velocity. A general expression is obtained which gives the order of magnitude of the dispersion coefficient for all Peclet numbers within the Darcy regime of the liquid convective velocities. This expression shows that for very small Peclet numbers, only the molecular diffusion provides the dominant contribution, whereas for intermediate values of Peclet numbers, both the liquid convection and the molecular diffusion contribute to the dispersion coefficients; in this range the dispersion coefficients are not linear in the liquid convective velocity. These findings are well supported by existing experimental observations. These theoretical insights into dispersion at the Darcy scale are also important in explaining the so-called macrodispersion and the scale effect at field scales. (Author's abstract)

STEADY STATE FLUID RESPONSE IN FRACTURED ROCK: A BOUNDARY ELEMENT SOLUTION FOR A COUPLED, DISCRETE FRACTURE CONTINUUM MODEL,
Royal Inst. of Tech., Stockholm (Sweden). Dept. of Water Resources Engineering.
A. M. Shapiro, and J. Andersson.
Water Resources Research, Vol. 19, No. 4, p 959-969, August, 1983. 10 Fig, 19 Ref.

Descriptors: *Fractures, *Groundwater movement, *Aquifers, Mathematical models, Geohydrology, Porous media.

A discrete fracture representation of a highly fractured groundwater aquifer is inappropriate as a modeling approach since the location of all fractures can never be explicitly specified. However, the alternative of exclusively employing a continuum description of the medium then neglects any geologic information that exists with regard to the location of specific fractures in such formations. In order to take better advantage of geologic information in highly fractured aquifers a model is proposed which couples the discrete fracture and continuum conceptualizations. In regions where discrete fractures are designated, an efficient means of computing the steady state fluid responses is formulated with the use of the boundary element method. This allows the consideration of highly complex fracture geometries, since fluid responses in the porous rock are described with a set of linear equations written only in terms of the hydraulic head and fluid mass flux at the boundaries the porous rock shares with the fractures. One-dimensional equations of fluid movement in the fractures written in terms of the same variables make coupling of the two systems straight forward. In this technique, discretization only along the fractures is required. Thus the internal discretization of the host rock that would be characteristic in the use of finite difference and finite element methods is alleviated. At the boundary of the region where specific fractures are identified, a continuum conceptualization is coupled to the discrete fracture model. Steady state fluid responses in the continuum domain are defined using a semianalytic technique which is based on the discretization of Green's third identity. The resulting coupled model allows the discrete fracture and continuum conceptualizations to be employed in the modeling of those areas where they are judged to be most appropriate, based on the availability of physical information. riptors: *Hydrodynamics, *Soil water, Stabili-nalysis, Computer models, Mathematical ls, Unsaturated flow, Infiltration, Porous .

odynamic stability analysis is applied to the ty of several soil water systems some of are potentially unstable. The first stage in alysis requires the generation of water con-nd pressure head profiles using a computer-numerical solution for the flow equation for rated porous materials. These profiles permit lculation of certain differential terms which r in the specification of the coefficients re-l in the stability analysis. Results for growth f imposed disturbances of wavelengths of 1, 25 cm together with the appropriate eigen-rs are presented for infiltration into a homo-us profile, redistribution following infiltra-nfiltration into a scale hetergeneous medium, nfiltration into a fine-over-coarse stratified e. Although instability was expected for the ribution, heterogeneous, and layered systems, esults, while showing a noticeable trend d instability, did not predict the occurrence h a condition. All the analyses have been d out with initial water contents of 0.05 cu cm. Small amounts of initial water can have ificant effect on the damping-out of instabil-hat otherwise would occur under dry initial ions. (Moore-IVI)

E ELEMENT TECHNIQUES FOR MOD-G GROUNDWATER FLOW IN FRAC-D AQUIFERS,
rans, Inc., Reston, VA.
Huyakorn, B. H. Lester, and C. R. Faust.
Resources Research, Vol. 19, No. 4, p 1019-August, 1983. 17 Fig, 5 Tab, 29 Ref. DOE ct E512-02900.

iptors: *Groundwater movement, *Geologic es, Mathematical models, Simulation, s media, Aquifers, Confined aquifers, Hy-c gradients.

lternative conceptual models of groundwat-v in fractured aquifers are considered. The ree are based on the dual-porosity approach ifferent representations of fluid interactions en the fractures and porous matrix blocks, e fourth is based on the discrete fracture ch. Two numerical solution techniques are ted for solving the governing equations asso-with the dual-porosity flow models. In the chnique the Galerkin finite element method to approximate the equation of flow in the e domain and a convolution integral is used cribe the leakage flux between the fractures rous matrix blocks. In the second the Galer-ite element approximation is used in con-n with a one-dimensional finite difference imation to handle flow in the fractures and blocks, respectively. Both numerical tech-are readily amendable to the governing ns of the discrete fracture flow model. To the proposed numerical tecniques and com-arious conceptual models, four simulations roblem involving flow to a well fully pene-a fractured confined aquifer were per-l. Each simulation corresponded to one of r conceptual models. For the three simulat-es, where analytical solutions are available, merical and the analytical solutions were red. Both solution techniques yielded good with relative coarse spatial and temporal izations. Greater accuracy was achieved by mbined finite element-convolution integral que for early time values at which steep lic gradients occurring near the fracture-interface could not be accommodated by near finite difference approximation. For cases involving transient simulation of leakage from the matrix blocks to fractures, greater accuracy was achieved by the combined finite element-convolution technique. The combined finite element-convolution technique should be used in preference to the combined finite element-finite difference technique if greater accuracy is required in the early time simulation. DEVELOPMENT OF REACTION MODELS FOR GROUND-WATER SYSTEMS,
Geological Survey, Reston, VA.
L. N. Plummer, D. L. Parkhurst, and D. C. Thorstenson.
Geochimica et Cosmochimica Acta, Vol. 47, No. 4, p 665-686, April, 1983. 3 Fig, 9 Tab, 46 Ref.

Descriptors: *Geochemistry, *Groundwater, *Reaction models, Thermodynamics, Mass balance, Simulation, Reaction paths, Dolomite, Carbon isotopes, Sulfur isotopes, Gypsum, Ferric hydroxide, Pyrite, Carbon dioxide, Organic carbon, Florida.

Methods are described for developing geochemical reaction models from the observed chemical compositions of ground water along a hydrologic flow path. The roles of thermodynamic speciation programs, mass balance calculations, and reaction-path simulations in developing and testing reaction models are contrasted. Electron transfer is included in the mass balance equations to properly account for redox reactions in ground water. The mass balance calculations determine net mass transfer models which must be checked against the thermodynamic calculations of speciation and reaction-path programs. Although reaction-path simulations of ground-water chemistry are thermodynamically valid, they must be checked against the net mass transfer defined by the mass balance calculations. An example is given testing multiple reaction hypotheses along a flow path in the Floridan aquifer where several reaction models are eliminated. Use of carbon and sulfur isotopic data with mass balance calculations indicates a net reaction of incongruent dissolution of dolomite (dolomite dissolution with calcite precipitation) driven irreversibly by gypsum dissolution, accompanied by minor sulfate reduction, ferric hydroxide dissolution, and pyrite precipitation in central Florida. Along the flow path, the aquifer appears to be open to CO2 initially, and open to organic carbon at more distant points down gradient. (Author's abstract)

SANDSTONE WATER SENSITIVITY: EXISTENCE OF A CRITICAL RATE OF SALINITY DECREASE FOR PARTICLE CAPTURE,
Michigan Univ., Ann Arbor. Dept. of Chemical Engineering.
K. C. Khilar, H. S. Fogler, and J. S. Ahluwalia.
Chemical Engineering Science, Vol. 38, No. 5, p 789-800, 1983. 15 Fig, 3 Tab, 10 Ref. NSF grants NSF-G-ENG79-06647, NSF CPE 8108197.

Descriptors: *Sandstones, *Salinity, *Permeability, Clay, Water sensitivity, Groundwater movement, Particle capture, Clogging, Pores, Mathematical models, Berea sandstone.

A critical rate of salinity decrease (CRSD) was found to exist in the water sensitivity of Berea sandstone. The CRSD was determined by conducting core flood experiments in which the salinity was decreased exponentially by placing mixers of various volumes in the inlet stream. The CRSD is equal to a space velocity of 0.40/hr at a superficial velocity of 25.6 cm/hr. The superficial velocity has a significant effects on the CRSD. At a velocity of 2.4 cm/hr, the CRSD is equal to a space velocity of 0.10/hr. The CRSD decreases with decreasing velocity. Above the CRSD, drastic reductions in core permeability occur due to a log jam, or bridging effect, at the pore constriction. Below the CRSD, the released clay particles pass through the constriction without being captured and therefore very little reduction in core permeability occurs. A critical particle concentration was also identified above which bridging occurs. A mathematical model developed to delineate the regions of high and low permeability reductions was found to be in good agreement with experimental measurements. (Moore-IVI)

COMMON COMPOSITION CHARACTERISTICS OF FLUORIDE BEARING GROUNDWATERS,
Andhra Univ., Waltair (India). Dept. of Geophysics.
V. V. J. Sarma, and A. N. Swamy.
Water, Air and Soil Pollution, Vol. 20, No. 1, p 29-39, July 1983. 6 Fig, 1 Tab, 12 Ref.

Descriptors: *Groundwater, *Fluoride, Visakhapatnam basin, India, Calcium, Magnesium, Sodium, Sodium carbonate, Alkalinity.

During routine groundwater surveys of the Visakhapatnam basin, concentrations of fluoride ions above the permissible limit of 1 to 1.5 mg/l were detected near the village of Jaggayyapalem in Andhra Pradesh State, India. The fluoride bearing groundwaters of the area were compared with fluoride bearing groundwaters from different parts of the world. In general, there exists a good linear negative relationship between F(-) and Ca(2+) plus Mg(2+) ions, and a linear positive relationship between F(-) and HC03(-) ions in high fluoride bearing groundwater. Most of the fluoride bearing waters contain high to very high amounts of Na and are classified as high to very high alkali hazard waters. Almost all the waters contain very high amounts of residual sodium carbonate, exceeding the maximum value of 2.5 meq/l. (Moore-IVI)

PASSIVE MICROWAVE SENSING OF SOIL MOISTURE CONTENT: THE EFFECTS OF SOIL BULK DENSITY AND SURFACE ROUGHNESS,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
J. R. Wang.
Remote Sensing of Environment, Vol. 13, No. 4, p 329-344, September, 1983. 8 Fig, 1 Tab, 25 Ref.

Descriptors: *Soil water, *Radiometry, *Measuring instruments, Soil density, Physical properties, Remote sensing.

Microwave radiometric measurements over bare fields of different surface roughness were made at frequencies of 1.4 GHz, 5 GHz, and 10.7 GHz to study the frequency dependence, as well as the possible time variation, of surface roughness. An increase in surface roughness was found to increase the brightness temperature of soils and reduce the slope of regression between brightness temperature and soil mositure content. The frequency dependence of the surface roughness effect was relatively weak when compared with that of the vegetation effect. Radiometric time-series observations over a given field indicate that field surface roughness might gradually diminish with time, especially after a rainfall or irrigation. The variation of surface roughness increases the uncertainty of remote soil moisture estimates by microwave radiometry. Three years of radiometric measurements over a test site revealed a possible inconsistency in the soil bulk density determination, which is an important factor in the interpretation of radiometric data. CALCULATION OF SORPTIVITY FROM CONSTANT-RATE RAINFALL INFILTRATION MEASUREMENT,
Southern Illinois Univ. at Carbondale. Dept. of Forestry.
S.-K. Chong.
Soil Science Society of America Journal, Vol. 47, No. 4, p 627-630, July-August, 1983. 3 Fig, 21 Ref.

Descriptors: *Ponding, *Rainfall infiltration, *Sorptivity, Rainfall-runoff relationships, Permeability coefficient, Soil hydraulics, Hawaii.

Incipient ponding time equations were rearranged and used for calculating sorptivity under constant-rate rainfall conditions. The equations were tested using the field-measured data obtained in Hawaii. The incipient ponding time is assumed equal to the time of first appearance of runoff from the experimental plot. Additionally, the A value in the Philip two-term infiltration equation is assumed to be Ksat/3. The sorptivity values calculated from both equations have only a 1.22% difference. The accuracy of the calculated sorptivity was assessed by its use for predicting infiltration. In the comparison of cumulative infiltration, the correlation coefficient between measured and estimated values is > 0.9 with a mean error percentage of 20.09 and a median of 10.57%. The equation requires information on rainfall intensity, saturated hydraulic conductivity, and the incipient ponding time. Even though the time to incipient ponding and the time of first appearance of runoff were different, the assumption that they are equal is acceptable for runoff plots within uniform slopes. Using rainfall infiltration to measure sorptivity is impractical since the experiment requires tremendous time and labor. It is possible to calculate sorptivity from the simulated rainfall-runoff experiment. (Moore-IVI)

SOIL WATER DIFFUSIVITY NEAR SATURATION,
Department of Scientific and Industrial Research, Palmerston North (New Zealand). Div. of Plant Physiology.
B. E. Clothier, and R. A. Wooding.
Soil Science Society of America Journal, Vol. 47, No. 4, p 636-640, July-August, 1983. 6 Fig, 18 Ref.

Descriptors: *Soil water, *Diffusivity, *Soil saturation, *Water retention, Moisture tension, Permeability coefficient, Soil absorption capacity.

Many laboratory porous materials are considered to have a zone of tension-saturation in their water retentivity curve near saturation, which implies that the soil water diffusivity, D, is infinite in such a region. Three new methods of measuring the diffusivity near saturation are presented. The soil used in all experiments was the fine sand-textured C horizon of Manawatu fine sandy loam, a Dystric Fluventic Eutrochrept. All methods found D to be finite, yet large, having a value of approximately 0.001 to 0.002 sq m/s. Since the near-saturated conductivity of the sand is of the order 10 to the -5 m/s this implies that the water retentivity curve near saturation has a finite but large slope of order 100 m. This was compatible with the measured retentivity data. The theory of one-dimensional absorption implies that the slope of the Boltzmann variable with respect to volumetric water content near saturation equals twice D divided by the sorptivity. The slope calculated this way was compatible with that found in absorption experiments. (Moore-IVI)

EFFECT OF SLOPE ON WATER BALANCE UNDER CENTER-PIVOT IRRIGATION,
Nebraska Univ.-Lincoln. Dept. of Agronomy.
A. Y. Hanna, P. W. Harlan, and D. T. Lewis.
Soil Science Society of America Journal, Vol. 47, p 760-764, July-August, 1983. 3 Fig, 5 Tab, 10 Ref.

Descriptors: *Soil water, *Slope, *Center-pivot irrigation, Water storage, Water balance, Surface runoff, Soil infiltration, Evapotranspiration, Corn, Sprinkler irrigation, Soil drainage, Rainfall-runoff relationships, Nebraska, Gage County.

The effects of slope on water storage and other water balance components under center-pivot irrigation were studied in Gage County, Nebraska. Soil water, surface runoff, precipitation, and irrigation were measured for soils of low infiltration on slopes of 2, 4, and 8% under corn (Zea mays L.). Evapotranspiration was calculated. Soil water content (0- to 137-cm depth) during the growing season was higher in soils on 8% slopes than in soils on slopes of 2 and 4%. Runoff from all slopes was not associated with sprinkler irrigation in the crop production system studied. As slope increased, surface runoff caused by rain increased, and internal drainage beyond the 137-cm depth decreased at approximately the same rate. The overall water depletion during the growing season was not significantly affected by slope. (Author's abstract)

MODELS FOR ESTIMATING IN-SITU POTENTIAL EXTRACTABLE WATER USING SOIL PHYSICAL AND CHEMICAL PROPERTIES,
Texas Agricultural Experiment Station, College Station.
D. K. Cassel, L. F. Ratliff, and J. T. Ritchie.
Soil Science Society of America Journal, Vol. 47, No. 4, p 764-769, 1983. 2 Fig, 4 Tab, 15 Ref.

Descriptors: *Soil properties, *Moisture availability, Soil water, Physical properties, Chemical properties, Model studies, Estimating.

Accurate evaluation of the upper and lower limits of soil water availability is vital for accurate computation of the water balance in marginally dry regions. Empirical equations were developed for calculation of the limits of in situ potential extractable soil water using routinely measured soil proerties. Physical and chemical properties were determined on samples collected from depth increments coinciding with measurements of extractable water limits. The potential extractable water calculated as the difference between the upper and lower limits based upon the equations developed was correlated with measured plant extractable water for the different levels of input information and textural separations. The coefficients of determination for potential extractable water ranged from 0.375 for the two-variable input level with no textural separation to 0.758 for the 10-input level with three textural separations. Standard deviation for the latter, best correlated system to estimate potential extractable water was about 2 percentage units when compared with field measured extractable water. (Baker-IVI)

FIELD-MEASURED LIMITS OF SOIL WATER AVAILABILITY AS RELATED TO LABORATORY-MEASURED PROPERTIES,
Texas Agricultural Experiment Station, College Station.
L. F. Ratliff, J. T. Ritchie, and D. K. Cassel.
Soil Science Society of America Journal, Vol. 47, No. 4, p 770-775, July-August, 1983. 6 Fig, 3 Tab, 9 Ref.

Descriptors: *Soil water, *Water availability, Crops, Water supply, Soil properties.

The accurate evaluation of soil water reserves available for plant use is vital in developing optimum water management for crop production in marginally dry regions. A comprehensive data base of field measured upper and lower limits of soil water reservoir was obtained and evaluated. The field measured upper limit was taken as the water content at which drainage from a prewetted soil had practically ceased. The lower limit was taken as the water content of the soil at which plants were practically dead or dormant as a result of the soil water deficit. Variation often exist within a soil series at a particular site for the fi measured upper and lower limits. However, differences between the field-measured limits, total available water reservoir, were relative constant. Crop species caused only minor diff ences in the lower limit water content for upper part of the soil profile where root leng density was apparently above some critical lev However, some annuals extracted water to grea depths than others. If absolute accuracy is nec sary in water balance calculations, laboratory e mated soil water limits should be used with caut and field measured limits would be preferre (Baker-IVI)

CHARACTERIZING UNSATURATED HYDRAULIC CONDUCTIVITY OF WESTERN KENTUCKY SURFACE MINE SPOILS AND SOILS,
Kentucky Agricultural Experiment Station, Lexington. Dept. of Agronomy.
A. Ward, L. G. Wells, and R. E. Phillips.
Soil Science Society of America Journal, Vol. 47, No. 5, p 847-855, September-October, 1983. 9 Fig, 2 Tab, 21 Ref.

Descriptors: *Permeability coefficient, *Soil infiltration, *Spoil banks, *Mine wastes, *Strip mine wastes, Mathematical models, Soil water, Soil saturation.

A large-scale laboratory infiltrometer system was used to determine infiltration characteristics of 'reconstructed' surface mine spoil and soil horizons. Soil water characteristic curves were determined using the Brooks-Corey and the Gardner procedures and developed based on desorption tensiometer data. Unsaturated hydraulic conductivity values were determined using the 'plane of zero flux' procedure and compared with predictions resulting from models described by Campbell, Burdine, and Mualem for situations involving reconstructed soil and spoil materials. There was generally good agreement between the models and excellent agreement between Campbell's predictions and plane of zero flux results. Both the Gardner equation and the Brooks-Corey equation gave good estimates of the soil water characteristic curves for the materials. The physical significance of the parameters Theta sub r, and Psi sub e when determined by statistical procedures, appears very questionable. In this study, the final steady-state infiltration rate appeared to be a good estimate of the hydraulic conductivity at apparent saturation. (Author's abstract)

LAKE TEMPERATURE DYNAMICS IN HYBRID COOLING SYSTEM,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
T. W. Sturm, J. M. Fulford, and K. J. Fay.
Journal of Environmental Engineering, Vol. 109, No. 3, p 668-684, June, 1983. 10 Fig, 24 Ref. NSF grant ENG78-21957.

Descriptors: *Cooling lakes, *Simulation, *Thermal properties, Thermal pollution, Solar heating, Cooling water, Wind, Advection, Diffusion, Water temperature, Thermal stratification, Water circulation, Epilimnion, Indiana.

nsient thermal simulation model of a hybrid
ng lake is developed to assess the impact of
ng water withdrawals and cooling tower dis-
es on the thermal structure of the lake. The
l is based on one-dimensional mechanical and
al energy balances and includes the physical
sses of solar heating, wind stirring, vertical
tion, and hypolimnetic diffusion. Tempera-
data were collected on two small lakes in
ern Indiana, and the simulated temperatures
mpared with the measured data for the lake
fication seasons of 1976 and 1978. Cooling
circulations significantly thicken the epilim-
due to vertical advection of heat. This is
rmed by the observed variation of three di-
onless parameters which characterize the es-
l physical processes that affect the lake ther-
tructure. These parameters are a wind Rich-
n number, a withdrawal densimetric Froude
er, and a dimensionless surface buoyancy
The simulation model can be used to quantify
ermal response of the lake due to a change in
ithdrawal densimetric Froude number while
ther two dimensionless parameters remain
nged. (Moore-IVI)

fluxes of water, chloride, silicate and various
s of nitrogen and phosphorus into and out of a 3925 ha impoundment (Lake Talquin) in north Florida were examined over a 3 year period. Annual hydraulic flushing rates for the lake varied by a factor of more than 2 during the study period and provided an opportunity to examine the effect of flushing rate on nutrient cycling within the lake. The results support the hypothesis that nutrient retention and transformation in lakes and impoundments with high flushing rates (>1/year) are appreciably influenced by annual variations in flushing rates. Higher fractions of input silicate and total phosphorus were retained by Lake Talquin during the years with average flushing rates (8/year) than during a year with abnormally high flushing rate (16/year). Nitrogen was not appreciably retained during any of the three study years, and thus N:P ratios in the lake outflow were higher than in the inflow. Phytoplankton productivity was appreciably higher (70%) during the year with the higher flushing rate, apparently in response to higher reactive phosphorus concentrations in the lake and perhaps to a higher standing crop of phytoplankton during that year. Reactive phosphorus and dissolved inorganic nitrogen inputs could account for only about 30% and 25%, respectively, of the phosphorus and nitrogen required to support observed photosynthetic rates in all three study years. Recycling of nutrients apparently accounted for most of the remainder, although nitrogen fixation could not be ruled out as a factor in the nitrogen budget. (Author's abstract)

INFLUENCE OF ELEVATED NITRATE CONCENTRATION ON RATE OF LEAF DECOMPOSITION IN A STREAM,
Georgia Univ., Athens. Dept. of Zoology.
J. L. Meyer, and C. Johnson.
Freshwater Biology, Vol. 13, No. 2, p 177-183, April, 1983. 5 Fig, 2 Tab, 25 Ref.

Descriptors: *Organic matter, *Litter, *Decomposition, Forest watersheds, Nutrients, Streams, Nitrates, Phosphorus, Nitrogen, Environmental effects, Ecosystems.

Leaf decomposition was compared in two streams at the Coweeta Hydrologic Laboratory, North Carolina. One stream drains an undistributed hardwood watershed, while the other drains a successional watershed subject to an insect outbreak. The successional watershed has elevated nitrate concentrations in the streamwater. Both black locust (Robinia pseudo-acacia) and sweet birch (Betula lenta) leaf litter decomposed 2.8 times more rapidly in the stream with high nitrate concentrations. The more rapid decay rates appeared to be partly due to accelerated microbial processing in response to nitrate enrichment, because microbial biomass (as ATP) was higher in the nitrate-enriched stream. At each point in time, nitrogen and phosphorus content of the litter was lower in the high nitrate stream; however, there was no significant difference in nitrogen or phosphorus content at the same state of leaf decay in the two streams. Natural watershed disturbances such as insect infestations or anthropogenic disturbances such as clear cutting, by increasing the nitrate content of stream water, can alter rates of detrital processing in streams. In a detritus-based ecosystem a change in detrital processing rates could profoundly affect stream ecosystem function. (Baker-IVI)

CONTINUOUS AMMONIUM ENRICHMENT OF A WOODLAND STREAM: UPTAKE KINETICS, LEAF DECOMPOSITION, AND NITRIFICATION,
Oak Ridge National Lab., TN. Environmental Sciences Div.
J. D. Newbold, J. W. Elwood, M. S. Schulze, R. W. Stark, and J. C. Barmeier.
Freshwater Biology, Vol. 13, No. 2, p 193-204, April, 1983. 6 Fig, 4 Tab, 36 Ref.

Descriptors: *Streams, *Sediments, *Ammonium, *Enrichment, Nitrification, Nitrogen, Adsorption, Benthic environment, Nitrates, Tennessee, Walker Branch.

In order to test for nitrogen limitation and examine ammonium uptake by stream sediments, ammonium hydroxide was added continuously at concentrations averaging 100 micrograms/liter for 70 days to a second-order reach of Walker Branch, an undisturbed woodland stream in Tennessee. Ammonium uptake during the first 4 hr of addition corresponded to adsorption kinetics rather than to first-order uptake or to Michaelis-Menten kinetics. However, the calculated adsorption partition coefficient was two to four orders of magnitude greater than values reported for physical adsorption of ammonium, suggesting that the uptake was largely biotic. Mass balance indicated that the uptake of ammonium from the water could be accounted for by increased nitrogen content in benthic organic detritus. Nitrification, inferred from longitudinal gradients in NO3, began soon after enrichment and increased dramatically near the end of the experiment. Both ammonium and nitrate concentrations dropped quickly to near background levels when input ceased, indicating little desorption or nitrification of excess nitrogen stored in the reach. There was no evidence of nitrogen limitation as measured by weight loss, oxygen consumption, phosphorus content, and macroinvertebrate density of red oak leaf packs, or by chlorophyll content and aufwuchs biomass on plexiglass slides. A continuous phosphorus enrichment 1 year earlier had demonstrated phosphorus limitation in Walker Branch. (Author's abstract)

PHOSPHORUS AND CALCIUM CARBONATE SOLUBILITIES IN LAKE KINNERET,
Technion - Israel Inst. of Tech., Haifa.
Y. Avnimelech.
Limnology and Oceanography, Vol. 28, No. 4, p 640-645, July, 1983. 2 Fig, 2 Tab, 19 Ref.

Descriptors: *Lakes, *Chemical properties, Algal growth, Phosphates, Calcium, Nutrients, Lake Kinneret, Calcium carbonate.

Phosphate and calcium carbonate solubilities were calculated from data obtained for near-bottom water samples from Lake Kinneret during the years 1975-1977. A potential diagram technique was used to determine which solid phase is in equilibrium with the solution. Both phosphorus and calcium carbonate solubilities are controlled, during the January-August period, through equilibrium with calcium-carbonate-phosphate. The calcium carbonate ionic product changes, depending on the phosphoric acid potential, during this period. Calcium carbonate activity is constant during the last months of the stratified period (September-December). These findings support the hypothesis that the first and most reactive product of the reactions occurring between calcium carbonate and phosphorus is a CaCO3H3PO4 surface complex. (Baker-IVI)

EFFECTS OF REGULATION OF THE RIVER TEES UPON FISH POPULATIONS BELOW COW GREEN RESERVOIR,
D. T. Crisp, R. H. K. Mann, and P. R. Cubby.
Journal of Applied Ecology, Vol. 20, No. 2, p 371-386, August, 1983. 4 Fig, 13 Tab, 13 Ref.

Descriptors: *Fish populations, *Reservoirs, *Environmental effects, Seasonal variation, Population density, Green reservoir, River Tees.

The population density, growth, biomass, fecundity and production of bullhead (Cottus gobio) and brown trout (Salmo trutta) were estimated in the River Tees below the regulating reservoir at Cow Green. Comparisons were made with estimates obtained for the same site before impoundment, and with data from Maize Beck, and unregulated tributary of the Tees below the reservoir. Changes in the growth of trout were negligible, but there was an apparent decrease in the observed lengths of O group bullheads in the regulated Tees. This may reflect a shorter growing season because bullheads spawned later in the Tees after impoundment, possibly in response to the delay in the increase in water temperature during the spring. There were marked annual variations in the numbers of brown trout and bullhead, but population

densities of both species increased in the Tees following regulation. The numbers of both species were significantly higher in the Tees than in Maize Beck during both periods. The annual instantaneous mortality rate of bullheads increased from 0.67 to 1.30 in the Tees following impoundment; corresponding values for Maize Beck were 0.68 and 0.81. The mean fecundity of individual female bullheads of any given size decreased in the Tees, but remained the same in Maize Beck. The increase in population density in the Tees caused a significant increase in the number of eggs laid each year by the whole population from 3.70 to 8.42 eggs/sq m. The corresponding values in Maize Beck of 2.04 and 2.28 eggs/sq m were not significantly different. Only very approximate values were obtained for annual production of trout. Estimated bullhead production increased slightly at Maize Beck and by a factor of three in the Tees. Annual production by older fish changed little. The combination of environmental changes caused by regulation has improved conditions for the downstream fish populations. This has been exploited by the bullheads and trout mainly through increased population density and population biomass, rather than through any marked increased in the growth rate of individual fish. This would be expected because growth rate appears to be limited mainly by water temperature. (Baker-IVI)

FISH OF CHANNELIZED AND UNCHANNELIZED SECTIONS OF THE BUNYIP RIVER, VICTORIA,
James Cook Univ. of North Queensland, Townsville (Australia). School of Biological Sciences.
K. G. Hortle, and P. S. Lake.
Australian Journal of Marine and Freshwater Research, Vol. 34, No. 3, p 441-450, 1983. 1 Fig, 6 Tab, 26 Ref.

Descriptors: *Fish population, *Channeling, *Environmental effects, Rivers, Streams, Population density, Bunyip River, Australia.

The distribution and abundance of fish at three channelized and three unchannelized sites on the Bunyip River in southern Victoria were investigated. Ten species of native fish, including the Australian grayling (Prototroctes maraena), and two species of introduced fish were collected in three sets of seasonal samples by electrofishing. The unchannelized sites and a channelized site directly above a small weir had significantly higher species richness, total fish biomass, numerical density and standing crop than the other two channelized sites. Ammocoete lamprey larvae, short-finned eels, southern pigmy perch and brown trout were most abundant at the unchannelized sites, whereas the common jollytail was most abundant at the channelized sites. Total numbers and biomass of fish and species richness were all positively correlated with the area of snags present, and species richness and fish biomass correlated positively with the area of slack water. It appears that the absence of suitable habitat (viz, area of snags, area of slack water, length of bank fringed with vegetation) accounts for the lower abundance and lower species richness of fish after channelization. A small weir at one of the channelized sites ameliorated partly the effects of channelization. (Author's abstract)

EARLY EUTROPHICATION IN THE LOWER GREAT LAKES: NEW EVIDENCE FROM BIOGENIC SILICA IN SEDIMENTS,
Michigan Univ., Ann Arbor. Great Lakes Research Div.
C. L. Schelske, E. F. Stoermer, D. J. Conley, J. A. Robbins, and R. M. Glover.
Science, Vol. 222, No. 4621, p 320-322, October, 1983. 2 Fig, 1 Tab, 27 Ref.

Descriptors: *Eutrophication, *Lakes, Diatoms, Sedimentation, Nutrients, Great Lakes, Lake Ontario, Lake Erie, Lake Michigan.

New evidence from studies of biogenic silica and diatoms in sediment cores related to eutrophication in the lower Great Lakes is presented. Diatom production peaked from 1820 to 1850 in Lake Ontario, at about 1880 in Lake Erie, but not until 1970 in Lake Michigan. The biogenic silica data from Lake Michigan and Lake Ontario cores indicate that the silica-depletion sequence occurred over a relatively short period of time, possibly as little as 20 to 40 years. This short time course shows that silica dynamics and mass-balance relations can be affected significantly and rapidly by biological effects of nutrient enrichment. Silica-limited steady states have developed in Lake Ontario and Lake Erie and possibly since 1970 in Lake Michigan. Lake Huron with recent increases in BSI storage may be in a transition between steady states whereas silica dynamics have been affected least in Lake Superior where phosphorus enrichment has been least. FISH COMMUNITIES ALONG ENVIRONMENTAL GRADIENTS IN A SYSTEM OF TROPICAL STREAMS,
Illinois Univ. at Urbana-Champaign. Dept. of Ecology, Ethology and Evolution.
P. L. Angermeier, and J. R. Karr.
Environmental Biology of Fishes, Vol. 9, No. 2, p 117-135, September, 1983. 10 Fig, 6 Tab, 46 Ref.

Descriptors: *Forests, *Streams, *Fish populations, Rainfall, Topography, Benthic environment, Behavior, Nutrients, Tropical regions, Panama, Trophic level.

Fish community structure was examined in 9 forested streams (1-6 m wide) in central Panama during dry seasons over a 3 year period. Study regions varied in annual rainfall, degree of canopy shading, and topographical relief. Benthic invertebrates were more abundant in riffles than in pools and more abundant in eary (January) than late (March) dry season. In addition, benthos abundances were negatively correlated with canopy shading among study regions. Terrestrial invertebrate abundances were greater in January than March and were correlated with stream width. Fishes were assigned to 7 feeding guilds (algivores, aquatic insectivores, general insectivores, piscivores, scale-eaters, terrestrial herbivores, omnivores) on the basis of similarity of gut contents. Four species exhibited marked dietary shifts with increasing size. Distributions of feeding guilds (biomass) among habitats and streams were not generally correlated with availabilities of their major food resources. All feeding guilds except aquatic insectivores were most concentrated (biomass per area) into deep pools. Densities of algivores and terrestrial herbivores increased with stream size, but the density of aquatic insectivores declined. Species richness of feeding guilds increased with stream size and canopy openness. The proportion of fish biomass supported by algae and terrestrial plant material increased with stream size, while that supported by aquatic and terrestrial invertebrates declined. Small fishes (< 40 mm TL) were most abundant in pools of small streams. Terrestrial predators appeared to be more important than food availability in determining distributions of fish among habitats. However, trophic diversity of fish communities may be related to the reliability of available food resources. (Author's abstract)

LEAF PROCESSING IN TWO CONTRASTING BEECH FOREST STREAMS: EFFECTS OF PHYSICAL AND BIOTIC FACTORS ON LITTER BREAKDOWN,
Canterbury Univ., Christchurch (New Zealand). Dept. of Zoology.
J. S. Rounick, and M. J. Winterbourn.
Archiv fur Hydrobiologie, Vol. 96, No. 1, p 448-474, April, 1983. 8 Fig, 4 Tab, 53 Ref.

Descriptors: *Organic matter, *Streams, *Litter, Forests, Forest watersheds, Biodegradation, New Zealand.

Changes in dry weight, protein and oxygen consumption of mountain beech leaves held in mesh bags in two New Zealand streams were investigated and interpreted in relation to the contrasting physical and faunal chacteristics of the streams. Weight losses were most rapid in coarse-mesh (5 mm) bags incubated in Middle Bush Stream, a relatively stable stream with a large population of shredders. In contrast, leaf breakdown rate in coarse-mesh bags held in Craigieburn Cutt Stream, a more unstable stream with few shredd was similar to that recorded in fine mesh (0.2 m containers in both streams. Leaves in bags bur in the beds of both streams lost weight m slowly than their surface counterparts and h slightly lower protein levels and respiration ra Larvae of the caddisfly, Zelandopsyche ingi were primarily responsible for the rapid disappe ance of beech leaves in Middle Bush Stream. A though apparently absent from Craigieburn C ting Stream, cage experiments showed that larv grew and survived equally well in both strea Absence of Z. ingens from Craigieburn Cutti Stream is attributed to the inability of the stream retain coarse particulate organic inputs. Retenti appears to be the key to shredder abundance a hence a major factor controlling litter breakdow In streams with poor retention capacities, the c ganic layers which develop on stone surfaces a the most important sites of carbon transfer to t benthos. Descriptors: *Phytoplankton, *Lakes, *Ecosys tems, Productivity, Zooplankton, Photosynthesis Kashmir, Dal Lake.

Dal Lake is situated in an urban environment an thus exposed to undesirable human influence which threaten its existence. The efficiency o energy utilization at various trophic levels of th lake has been studied. In Dal Lake ecosystem it ha been observed that through photosynthesis th system fixes about 1009 g out of which only 11% i contributed by phytoplankton and 88% by macro phytes. Periphyton accounts for less than 1% o primary production. Respiratory losses are quite high and on a yearly basis it comes to 69%. Zoo plankton fix about 0.41 g carbon/sq m/yr while fish harvest amounts to 0.165 g carbon/sq m/yr and 312.7 g carbon/sq m/yr are returned back to lake bottom. The conversion efficiency between primary producers and zooplankton is 0.17% and between former and fish it is 0.019%. Benthic population of the lake is insignificant. Thus most of the energy fixed by macrophytes is unutilized. In order to make good use of this component, introduction of grass carp is desirable. (Baker-IVI)

LIGHT INTENSITY AND RELATIVE LIGHT CHANGES AS FACTORS REGULATING STREAM DRIFT,
New Hampshire Univ., Durham. Dept. of Zoology.
J. F. Haney, T. R. Beaulieu, R. P. Berry, D. P. Mason, and C. R. Miner.
Archiv fur Hydrobiologie, Vol. 97, No. 1, p 73-88, May, 1983. 5 Fig, 2 Tab, 18 Ref.

Descriptors: *Light intensity, *Mayflies, Behavior, Daphnia, Population dynamics, Behavior, Drift.

Studies were conducted in two woodland streams to evaluate the importance of light intensity and relative rate of light change on the timing and density of mayfly drift. Under natural conditions light intensity ranged from 1.0-12.9 micro W/sq cm and relative light change from -.0024 to -.0036/sec at the time of the initiation of evening drift (EDI). When light intensity was reduced 85% by covering a section of the stream, light intensity at EDI was also lower and the timing of drift shifted, despite little difference in the relative light change. A model of light control of evening drift is proposed that involves the interaction of photokinetic

ity regulated by the relative change in light
hototactic behavior controlled by light inten-
The effect of moonlight on the pattern of drift

riptors: *Zooplankton, *Reservoirs, *Turbidi-
rganic matter, Adsorption, Aquatic life, Nu-
s, Daphnia.

rvoirs built on rivers draining agricultural wa-
eds are often turbid with suspended sedi-
s. Filter-feeding zooplankton, e.g., members
e genus Daphnia, seem to be as abundant in
reservoirs as in natural lakes. Using con-
d laboratory conditions, the potential role of
ended sediments in the nutrition of Daphnia
a turbid reservoir was investigated. In three
of experimental procedures measurements
made of: (1) the physical effect of sediments
ne ingestion and incorporation rates of algae
aphnids, (2) the ingestion rates of two sizes of
mineral sediment particles by daphnids, and
ne growth and survival of daphnids fed yeast
sediments with and without organic matter
rbed onto the particle surfaces. Increases in
ended sediment concentration from 0.0 to 2451
L decreased ingestion rates of 14C-labeled
rella vulgaris by Daphnia parvula and D.
x by about 95% and decreased incorporation
by 99%. Sediment concentrations of 50-100
L reduced the algal carbon ingested by daph-
to potential starvation levels. 65Zn-labeled
and coarse (1.88 and 4.65 micrometer mean
eter) clay mineral sediment particles were fed
. parvula, D, pulex, and D. similis. Ingestion
of sediments by daphnids were limted at
cle concentrations of about 5000000 particles/
and were dependent on particle size, daphnid
ies, and body size. Fine particles were ingested at greater rates by D. pulex and D. parvula than were coarse particles, while large D. similis ingested coarse and fine particles at similar rates. In addition, D. pulex had higher ingestion rates in each particle size suspension than did D. parvula or D. similis. The differential ability to ingest these particles suggests a mechanism of regulating daphnid species composition if the organic matter adsorbed to these sediment particles is useful as food. To evaluate this mechanism, dissolved organic protein was adsorbed to sediment particles. When D. pulex were fed the amended sediment suspension, they grew larger than when fed control sediments, but not as large as when fed yeast. D. parvula grew equally well when fed either yeast or amended sediments. Thus, dissolved organic matter can be made available for daphnic growth by the mechanism of adsorption. (Baker-IVI)

A METHOD FOR THE REDUCTION OF LAKE MODEL PREDICTION ERROR,
Duke Univ., Durham, NC. School of Forestry and Environmental Studies.
K. H. Reckhow.
Water Research, Vol. 17, No. 8, p 911-916, August, 1983. 1 Fig, 11 Ref.

Descriptors: *Lakes, *Error analysis, *Water quality, *Model studies, Water quality control, Phosphorus, Land use.

Recent work on methods of error analysis to accompany the application of lake models has not enjoyed great acceptance in part because of the magnitude of the error term. For the models that have undergone a rigorous error analysis, prediction errors for various water quality variables are often 30% or more. A procedure is proposed for the reduction of the error associated with the prediction of lake phosphorus concentration from land use and hydrologic data. Existing lake quality data are used in the prediction, and the model is employed only to project changes from the present state. This obviates the need to project all land use impacts with the model. Only those proposed to change are projected. The result is a substantial reduction in prediction error for many planning scenarios. (Baker-IVI)

LIGHT-PRODUCTIVITY MODEL FOR ONONDAGA LAKE, N.Y.,
Louisiana State Univ., Baton Rouge. Dept. of Civil Engineering.
S. D. Field, and S. W. Effler.
Journal of Environmental Engineering, Vol. 109, No, 4, p 830-844, August, 1983. 6 Fig, 1 Tab, 35 Ref.

Descriptors: *Primary productivity, *Light, New York, Onondaga Lake, Hypereutrophic lakes, Mathematical models, Photosynthesis, Water temperature, Chlorophyll a, Nutrients, Light attenuation, Seasonal variation, Quantum yield.

Two models were calibrated to the 1978 primary productivity conditions of nutrient-rich hypereutrophic Onodaga Lake, N.Y.; one was based on the approach of Bannister (Limnology and Oceanography, Vol. 19, 1974, p 1-12), the other on a more conventional format. The data base, necessary for model development, included continuously monitored incident photosynthetically active radiation (PAR), and 115 parallel measurements of water column temperature, PAR attenuation, chlorophyll a, primary productivity, and key nutrients. Values of key parameters for the Bannister model, obtained by evaluation of the data set, differed from those recommended in the literature. Both models effectively predicted seasonal and short-term trends in primary productivity for most of the study, though the Bannister model was slightly better. The Bannister model predictions were particularly sensitive to estimates of the maximum quantum yield of photosynthesis. The Bannister model is preferred on theoretical grounds, since it incorporates more fundamental and more constant parameters, and more properly accounts for temperature influences. PRIMARY PRODUCTIVITY IN A LARGE, TEMPERATE LAKE WITH RIVER INTERFLOW: KOOTENAY LAKE, BRITISH COLUMBIA,
National Water Research Inst., Vancouver (British Columbia).
S. Jasper, E. C. Carmack, R. J. Daley, C. B. J. Gray, and C. H. Pharo.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 3, p 319-327, March, 1983. 8 Fig, 1 Tab, 34 Ref.

Descriptors: *Phytoplankton, *Productivity, *Kootenay Lake, British Columbia, Chlorophyll, Water temperature, Photosynthesis, Euphotic zone, Light, Nutrients, River inflow, Stratification.

Phytoplankton productivity in a large, deep lake with river interflow was determined using an incubator method modified to include vertical distributions of chlorophyll and temperature together with continuous surface irradiance measurements. The annual average areal production, in 1977, was 170 g C/sq m with daily areal productions ranging from 100 to 2800 mg C/sq m. P max for all samples correlated well with chlorophyll a ($r=0.79$). No large horizontal trends in areal productivity or Pmax were found in the lake at any time of the year. However, pronounced differences with depth in the photosynthetic characteristics of populations within the euphotic zone were common during the stratified season. The two large inflowing rivers are thought to be important to the productivity of Kootenay Lake as they initiate the spring production peak and supply nutrients to the deeper phytoplankton populations during the summer and fall period.

EFFECTS OF CHANGES IN PH ON TRANSPARENCY AND THERMAL REGIMES OF LOHI LAKE, NEAR SUDBURY, ONTARIO,
Ontario Ministry of the Environment, Rexdale. Limnology and Taxonomy Section.
N. D. Yan.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 5, p 621-626, May, 1983. 4 Fig, 3 Tab, 19 Ref.

Descriptors: *Hydrogen ion concentration, *Acid lakes, *Transparency, *Thermal regime, Neutralization, Chlorophyll, Phytoplankton, Phosphorus, Epilimnion, Hypolimnion, Solar heating, Lohi Lake, Ontario.

Prior to experimental neutralization in the fall of 1973, the pH of Lohi Lake was 4.4. The pH was maintained at >6.0 by further small additions of base in 1974 and 1975, but it subsequently declined, reaching 4.74 by 1979. Secchi transparency (depth) averaged over the ice-free season in Lohi Lake varied from 5.6 to 9.3 m. Secchi depth was not correlated with chlorophyll concentrations, phytoplankton biomass or total phosphorus, but it was negatively correlated with pH. Secchi depth was positively correlated with thermocline depth, epilimnetic thickness, and hypolimnetic heating rates suggesting that acidification should result in deeper mixing zones and warmer hypolimnia in lakes. The most probable cause of the increase in hypolimnetic heating rate following re-acidification of the lake is increased direct solar heating of the hypo-

LIBRARY U. OF ILLINOIS-URBANA-CHAMPAIGN

limnetic waters because of increased light penetration. (Moore-IVI)

NUTRIENT LIMITATION IN TWO ARCTIC LAKES, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
G. A. McCoy.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 8, p 1195-1202, August, 1983. 7 Fig, 17 Ref. EPA contract EPA-78-D-X0378.

Descriptors: *Limiting nutrients, *Arctic lakes, *Alaska, Bioassay, Selenastrum, Phosphorus, Nitrogen, Phytoplankton, Standing crop, Dissolved oxygen, Chlorophyta, Primary productivity, Fertilizers.

Batch-culture algal bioassays of Selenastrum capricornutum were used to predict the limiting nutrient in two small arctic-tundra lakes in 1979. In 1980 bioassays were performed again, and fertilizer was added to the lakes to test the predictions made from the 1979 bioassay results. In 1980, after the addition of phosphorus fertilizer, phytoplankton standing crop increased about 10-fold. After the addition of nitrogen fertilizer, another 10-fold increase in phytoplankton growth was measured. Concurrently, maximum daytime dissolved oxygen increased from 100 to 150% saturation, and pH increased from 7.0 to about 9.2. Further additions of fertilizer in late August and early September 1980 caused no significant increase in primary production. If the nitrogen content of the lake water is increased but that of phosphorus is not, no increase in algal growth occurs. Growth increases with phosphorus additions, but the magnitude of this increase is determined by the available nitrogen. When additional nitrogen is supplied to the system, further increases in algal growth occur. When nitrogen and phosphorus are supplied in excess, physical factors such as light or temperature become limiting in the lakes. (Author's abstract)

ORTHOPHOSPHATE TURNOVER TIME IN SHALLOW PRODUCTIVE LAKES,
Alberta Univ., Edmonton. Dept. of Zoology.
E. E. Prepas.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 9, p 1412-1418, 2 Fig, 4 Tab, 21 Ref.

Descriptors: *Orthophosphate, *Productivity, *Lakes, Thermal stratification, Nutrients, Turnover time, Shallow lakes, Canada.

Orthophosphate turnover times were measured in 18 small and medium-sized lakes in western Canada. Turnover times in eight thermally stratified lakes were similar to those of other Canadian lakes: moderately rapid (up to 42 min) in the spring, increasing to very rapid (3-16 min) during July and August. Turnover times in the shallow (i.e. those which mixed intermittently during summer) productive lakes were far more variable, ranging from 17 min to 17 h in spring and 2 min to 36 h during July and August. For individual shallow lakes turnover times remained constant for particular summers. One shallow lake was studied over two summers. In the first summer, turnover times were extremely slow (7-36 h) and in the second summer they were extremely rapid (2-11 min). Therefore the mechanisms controlling nutrient limitation in shallow productive lakes are not constant, and can vary dramatically from year to year. (Author's abstract)

TROPHIC STATE CLASSIFICATION OF LAKES WITH AQUATIC MACROPHYTES,
Florida Univ., Gainesville. Center for Aquatic Weeds.
D. E. Canfield, Jr., K. A. Langeland, M. J. Maceina, W. T. Haller, and J. V. Shireman.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 10, p 1713-1718, October, 1983. 5 Tab, 33 Ref. Dept. of Agriculture cooperative agreement 58-7B30-0-177.

Descriptors: *Aquatic plants, *Macrophytes, *Phosphorus, *Trophic state, Nutrients, Lakes, Florida.

Conventional criteria for classifying trophic state emphasize conditions in the open water and ignore the nutrients, plant biomass, and production associated with macrophytes. A method is proposed for determining the potential water column nutrient concentration through adding the nutrients contained in macrophytes to those in the water. During September and October 1981, six Florida lakes with different limnological characteristics were sampled to determine the biomass of submersed aquatic macrophytes. In these lakes, total submersed macrophyte biomass ranged from 18,100 kg dry wt to 2,170,000 kg dry wt. For calculated potential water column phosphorus concentrations, 20-96% of the phosphorus was in the submersed macrophytes and the total water column phosphorus content (WCP) values were 1.2 to 26 times the measured open water concentrations. The effect of these macrophytes on WCP values and therefore on trophic state assessments depends on the amount of macrophytes relative to the total lake volume. Macrophytes have little effect on trophic state assessment when less than 25% of the phosphorus in the water column is associated with macrophytes and the mean macrophtye concentration in the lake is less than 1 g dry wt/cu m. HYDROGEOCHEMISTRY OF LAKE TURKANA, KENYA: MASS BALANCE AND MINERAL REACTIONS IN AN ALKALINE LAKE,
Massachusetts Univ., Amherst. Dept. of Geology and Geography.
R. F. Yuretich, and T. E. Cerling.
Geochimica et Cosmochimica Acta, Vol. 47, No. 6, p 1099-1109, June, 1983. 7 Fig, 5 Tab, 42 Ref.

Descriptors: *Geochemistry, *Mass balance, *Minerals, *Lake Turkana, Kenya, Interstitial water, Chemical reactions, Chloride, Sodium, Cation exchange, Calcium, Alkalinity, Sediments, Silicates, Alkaline lakes, Chemical precipitation.

Lake Turkana, in northwestern Kenya, is a closed-basin, alkaline (pH = 9.2) lake of moderate salinity (TDS = 2500 ppm). Principal ions are Na(+), HCO3(-) and Cl(-). The lake is essentially polymictic in the northern basin and little compositional variation occurs in surface water. The Omo River is the principal influent, providing some 80-90% of water input to the lake. Chloride has an apparent accumulation time of about 2500 years after accounting for burial of interstitial water. The bottom sediments are predominantly detrital and fine-grained, yet mineral-water reactions are very important for the geochemical budget. Ca(2+) is precipitated as calcite; Na(+) is removed as an exchangeable cation on smectite; Mg(2+) is probably incorporated into a Mg-silicate phase, most likely poorly-crystalline smectite, as it enters the lake water; K(+) may be used in illite regradation. Cation exchange is a very important process in the mass balance of this lake. Over 40% of incoming Na is removed as an exchangeable cation. After cation exchange and interstitial water burial, Na has a response time of 2650 years, which compares favorably with that of chloride. These processes seem to occur rapidly within the water mass of the lake; other reactions may be important in regulating interstitial water compositions. Several changes occur in the upper 3m of sediment: interstitial-water pH drops to 8.3 and alkalinity increases slightly with depth, SO4(2-) decreases slightly, and amorphous silica saturation is approached. These changes are a response to organic matter oxidation and the dissolution of unstable silicates rather than a reversal of reactions occurring in the lake water. High rates of sedimentation (up to 1 cm per year) may minimize the effects of diffusion between the interstitial waters and the lake water, although burial of interstitial water assumes considerable importance. COMPARISON OF THE FORMULATION FOR EDDY DIFFUSION IN TWO ONE-DIMENSIONAL STRATIFICATION MODELS,
Salford Univ. (England). Dept. of Civil Engineering.
B. Henderson-Sellers, M. J. McCormick, and D. Scavia.
Applied Mathematical Modelling, Vol. 7, No. 3, p 212-215, June, 1983. 1 Fig, 24 Ref. DOE contract DE-AC02-79EV10005.

Descriptors: *Thermal stratification, *Eddy diffusion, *Mathematical models, Lakes, Wind, Water circulation, Water depth.

Models for thermal stratification based on turbulent diffusion concepts by Henderson-Sellers (J. Limnol. Soc. sth. Afr. 1980, 6, 49); and by McCormick and Scavia (Water Resour. Res. 1981, 17, 305), are shown to be equivalent at large values of the Richardson number, Rj. At small Rj, the simpler model reverts to specification of the turbulent diffusion as a constant value. This simplification is also demonstrated to be a realistic approximation only at low wind speeds and for deep lakes. By comparison of these model types, a parameter B (previously empirically defined by McCormick and Scavia) is related conceptually to the lake depth, H. Both model types have been used with success in lake stratification simulations. The equivalence of the parameterizations for the eddy diffusion coefficient has been shown under the constraints of constant current shear, high Richardson number, and low wind speed. The differences lie in the treatment of areas of low diffusion rates: the Henderson-Sellers model uses the turbulent diffusion coefficient at all depths, whereas the other model specifies a critical depth below which the value of K is taken as the thermocline minimum. ANAEROBIC OXALATE DEGRADATION: WIDESPREAD NATURAL OCCURRENCE IN AQUATIC SEDIMENTS,
Geological Survey, Menlo Park, CA. Water Resources Div.
R. L. Smith, and R. S. Oremland.
Applied and Environmental Microbiology, Vol. 46, No. 1, p 106-113, July, 1983. 4 Fig, 3 Tab, 27 Ref.

Descriptors: *Oxalate, *Sediments, *Decomposition, Anaerobic conditions, Lake sediments, Mud flats, Salt marshes, Aquatic environments, Detritus, Saline lakes, Searsville Lake, Lake Tahoe, South San Francisco Bay, California, Big Soda Lake, Nevada.

Significant concentrations of oxalate (dissolved plus particulate) were present in sediments taken from a diversity of aquatic environments, ranging from 0.1 to 0.7 mmol/liter of sediment. These included pelagic and littoral sediments from two freshwater lakes (Searsville Lake, Calif., and Lake Tahoe, Calif.) a hypersaline meromictic, alkaline lake (Big Soda Lake, Nev.), and a South San Francisco Bay mud flat and salt marsh. The oxalate concentration of several plant species which are potential detrital inputs to these aquatic sediments ranged from 0.1 to 5.0% (wt/wt). In experiments with litter bags, the oxalate content of Myriophyllum sp. samples buried in freshwater littoral sediments decreased to 7% of the original value in 175 days. This suggests that plant detritus is a potential source of the oxalate within these sediments. (C-14)oxalic acid was anerobically degraded to (C-14)CO2 in all sediment types tested, with higher rates evident in littoral sediments than in the pelagic sediments of the lakes studied. The turnover time of the added (C-14)oxalate was less than 1 day in Searsville Lake littoral sediments.

total sediment oxalate concentration did not significantly between littoral and pelagic sedi- s and therefore did not appear to be control- the rate of oxalate degradation. However, n profiles of (C-14)oxalate mineralization and lved oxalate concentration were closely cor- ed in freshwater littoral sediments; both were est in the surface sediments (0 to 5 cm) and eased with depth. The dissolved oxalate con- ation (9.1 micromol/liter of sediment) was 3% of the total extractable oxalate (277 mi- ol/liter of sediment) at the sediment surface. e results suggest that anaerobic oxalate degra- n is a widespread phenomenon in aquatic sedi- s and may be limited by the dissolved oxalate entration within these sediments. Water In Plants

ER BUDGET OF AN EASTERN DECIDU- FOREST STAND,
Ridge National Lab., TN. Environmental Sci- Div.
Luxmoore.
Science Society of America Journal, Vol. 47, , p 785-791, July-August, 1983. 6 Fig, 1 Tab, f. DOE contract W-7405-eng-26.

riptors: *Soil water, *Soil water potential, er budget, *Forests, Hydraulic gradient, Sea- variation, Simulation, Mathematical models, otranspiration, Root zone.

water content and soil matric potential were ored during 2 years at two neighboring top sites in an oak-hickory stand on a Typic dult forest soil with cherty silt loam texture. aulic gradients and soil water contents ed distinct seasonal variation. Soil water dy- s and water budgets were simulated with a lant-atmosphere water flow model using rologic, soil, and plant characteristics esti- l for the two sites. A seasonal pattern of soil drainage and upward fluxes was predicted by the model that corresponded with the field-determined hydraulic gradients. Recharge of water up into the root zone (0- to 90-cm depth) from lower depths was predicted to contribute an average of 9 and 29% of the soil evaporation plus transpiration water loss at the two sites. Total evapotranspiration, including interception evaporation, was similar at the two sites; however, the greater upward water flux at one site compensated for the lower soil water capacity in the root zone at that site. There were significant differences between calculated and simulated daily drainage rates. Simulated soil water contents for the two study sites differed somewhat from measured values obtained on specific days. At longer time scales, the annual water budgets simulated for the sites were similar and were in reasonable agreement with measurements from a local watershed study. Annual evapotranspiration was predicted to be 74.5 cm for the ridge-top forest stand, somewhat higher than the average of 70.5 cm estimated for the whole watershed. (Author's abstract)

RELATIVE ERODIBILITY OF 20 CALIFORNIA RANGE AND FOREST SOILS,
California Univ., Davis. Dept. of Land, Air and Water Resources.
K. E. Trott, and M. J. Singer.
Soil Science Society of America Journal, Vol. 47, No. 4, p 753-759, July-August, 1983. 2 Fig, 6 Tab, 42 Ref.

Descriptors: *Soil erosion, *Erodibility, Mineralogy, Clays, Soil texture, Mathematical models, Universal Soil Loss Equation, California.

The Universal Soil Loss Equation's K nomograph may not account for all of the factors affecting erodibility of western upland soils. To further investigate this, laboratory rainfall simulation on 0.6- by 0.6-m plots of sieved soil at 9% slope was used to measure relative erodibility of 20 upland soils, including two soils from terraces of the Sacramento River. The most powerful predictor in a stepwise multiple regression of erodibility, on a mass basis, was a combined smectite plus vermiculite clay mineralogy term. Also included in the four-variable regression equation were bulk density, pyrophosphate-extractable Fe + Al, and the standard texture term M. R(2) for the equation was 0.800. Smectite plus vermiculite, M, a clay mineralogy-pyrophosphate Fe + Al interaction term, pH, organic matter, oxalate Fe + Al, and vermiculite were the seven significant terms in the equation predicting soil loss on a volume basis. This equation had an R(2) of 0.772. For now, the best available tool for predicting erodibilities of western upland soils appears to be the Universal Soil Loss Equation erodibilities nomograph. Because of the large differences in parent materials and soil-forming conditions that distinguish midwestern from western soils, consideration of soil mineralogy in future predictive work may improve the predictive capacity of the nomograph. There may be value in examining direct and indirect indicators of soil parent material and soil development with regard to predicting erodibility. (Moore-IVI)

MATHEMATICAL MODEL OF SOIL EROSION AND DEPOSITION PROCESSES: I. THEORY FOR A PLANE LAND ELEMENT,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
C. W. Rose, J. R. Williams, G. C. Sander, and D. A. Barry.
Soil Science Society of America Journal, Vol. 47, No. 5, p 991-995, September-October, 1983. 1 Fig, 17 Ref.

Descriptors: *Soil erosion, *Soil deposition, Mathematical models, Kinematic flow, Sedimentation, Rainfall detachment, Soil entrainment, Overland flow, Slope, Runoff.

A new mathematical model of soil erosion and deposition on a plane land element makes use of an approximate analytic theory of runoff on a plane assuming kinematic flow. Plane land elements are important landscape elements in both farmed and natural systems. Rates of the following simultaneously occurring erosion/deposition processes are represented mathematically: rainfall detachment, sediment deposition, and soil entrainment by overland flow. The concept of stream power is used in representing the entrainment process. The form of analysis reduces the first-order partial differential equation expressing conservation of mass of sediment to an ordinary differential equation, which can thus be solved analytically. This solution gives sediment concentration at any time as a function of distance down the plane in terms of four defined soil factors, the slope of the land, two separate cover factors, and the rainfall and runoff rates. The product of water flux and sediment concentration gives sediment flux at any time and position on the plane. (Moore-IVI)

MATHEMATICAL MODEL OF SOIL EROSION AND DEPOSITION PROCESSES: II. APPLICATION TO DATA FROM AN ARID-ZONE CATCHMENT,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
C. W. Rose, J. R. Williams, G. C. Sander, and D. A. Barry.
Soil Science Society of America Journal, Vol. 47, No. 5, p 996-999, September-October, 1983. 5 Fig, 2 Tab, 10 Ref.

Descriptors: *Soil erosion, *Soil deposition, *Arid lands, Runoff, Sediment concentration, Mathematical models, Sediment entrainment, Soil detachment, Overland flow, Arizona.

Mathematical theory for soil erosion and deposition processes on a plane land element was applied to data on runoff and sediment concentration as a function of time for nine runoff events from a small (1.3 ha) arid watershed in Arizona. Sediment concentration (and therefore sediment flux) vs. time measured at the exit to the watershed could be matched by the theory using particular values of two physically defined parameters. These two parameters are essentially the detachability of soil to rainfall, and the efficiency of sediment entrainment by overland flow. The first parameter had greatest effects on sediment concentration early in any runoff event, and the second parameter dominated later concentrations, thus allowing almost independent assessment of both parameters. The variation in soil detachability with mean depth of overland flow derived from the field data bore similarities to controlled laboratory observations. (Author's abstract)

EFFECT OF CROP RESIDUE, TILLAGE-INDUCED ROUGHNESS, AND RUNOFF VELOCITY ON SIZE DISTRIBUTION OF ERODED SOIL AGGREGATES,
N. P. Cogo, W. C. Moldenhauer, and G. R. Foster.
Soil Science Society of America Journal, Vol. 47, No. 5, p 1005-1008, September-October, 1983. 5 Fig, 16 Ref.

Descriptors: *Soil erosion, *Soil aggregates, *Tillage, *Crop residues, *Velocity, Plowing, Flow rate, Sediment transport, Conservation tillage, Roughness.

The percentages of eroded soil aggregates over 10 size classes ranging from 0.002 to 2.0 mm in diameter as affected by crop residue cover, tillage-induced roughness, and water flow velocity were investigated under field conditions using simulated rainfall. The soils used were a 4.5% slope Russell silt loam and a 6.5% slope Martinsville loam. With no vegetation present, the smallest eroded aggre-

gates came from a chisel-plowed surface while the largest came from chisel- and moldboard-plowed surfaces which had been disked. A no-till treatment gave intermediate values. The D50 size (the aggregate size which 50% of the aggregates exceed) in the absence of soil cover was 0.033, 0.032, 0.020, and 0.011 mm for chisel plow plus disk, moldboard plow plus disk, no-till and chisel plow, respectively. When soil was covered by residue, and size distribution of the eroded aggregates was not greatly different among the tillage treatments. The D50 size was reduced in this case to about 0.012 mm for all tillage systems. For no-till, the percentage of the eroded aggregates > 0.05 mm decreased exponentially (r(2) = 0.85) with an increase in residue cover. Under chisel plowing residue was not effective in reducing the quantity of larger aggregates in the runoff. An increase in flow rate caused an increase in water flow velocity which, in turn, caused a linear (r(2) = 0.94) increase in the percentage of the eroded aggregates > 0.05 mm, for chisel plowing. The results from this study were explained in terms of sediment trapping capacity of the soil surface, as well as runoff transport capacity. (Author's abstract)

CHARACTERISTIC PARAMETERS OF NONEQUILIBRIUM PROCESSES IN ALLUVIAL CHANNELS OF FINITE LENGTH,
Iowa Univ., Iowa City. Inst. of Hydraulic Research.
W. F. Jaramillo, and S. C. Jain.
Water Resources Research, Vol. 19, No. 4, p 952-958, August, 1983. 8 Fig, 25 Ref.

Descriptors: *Sediment transport, *Alluvial channels, Sedimentation, Model studies, Aggradation, Degradation.

An analytical solution for the characteristic parameters of the nonequilibrium processes of aggradation due to sediment augmentation and degradation due to sediment diminution in alluvial channels of finite length is presented. The analytical solution for small time agrees with that for a semiinfinite channel. The analytical solution is compared with the available experimental data. Aggradation and degradation processes are similar to each other and their characteristic parameters are governed by the same equations. The analytical solution for small time is identical to that for a semi-infinite reach. The latter may be considered as a special case of the more general solution presented. The deviation of the experimental data from the analytical results is due to the two simplifications introduced in the model. The experimental results agree with the analytical results for moderate values of sediment overloading. (Baker-IVI)

SEDIMENT DEPOSITION ESTIMATION FROM CESIUM-137 MEASUREMENTS,
Illinois Univ. at Urbana-Champaign. Dept. of Agricultural Engineering.
J. K. Mitchell, S. Mostaghimi, D. S. Freeny, and J. R. McHenry.
Water Resources Bulletin, Vol. 19, No. 4, p 549-555, August, 1983. 4 Fig, 5 Tab, 9 Ref.

Descriptors: *Soil erosion, *Sedimentation, Watershed management, Waterway vegetation, Buffers, Soil conservation, Sediment deposition, Water depth, Allerton watershed, 4-H Memorial Lake, Illinois.

The movement of fallout Cs-137 carried by soil particles was studied as an indicator of erosion and sedimentation in the Allerton watersheds and 4-H Memorial Lake located near Monticello, Illinois. Sediment deposition was greater in the waterway draining from watershed IB than in the waterway from watershed IA. At the average rate of 2.3 cm/yr of sediment deposition in the lake (from 1954 to 1979), there will be a loss of over 2 m of water depth in the next century. However, there appears to be a decreasing rate of sediment deposition in the 4-H Memorial Lake as a result of improved conservation practices on the watersheds and the increased effectiveness of vegetated waterways and buffers for retaining sediment. Descriptors: *Stripmines, *Soil erosion, *Land reclamation, Sediment deposition, Mathematical models, Rill erosion, Interrill erosion, Spatial distribution, Sediment transport, Pennsylvania.

A rill-interrill erosion model was applied to a mined and reclaimed area. Soil loss from the interrill areas was estimated by the Universal Soil Loss Equation (USLE). The model considers the fate and ultimate disposition of the sediment from interrill areas along with the fate and destination of soil materials detached by the rill flow. The net sediment loss was predicted by comparing, for a given flow, the amounts of eroded soil to rill transport capacity. The experimental area was a small reclaimed site in Central Pennsylvania. The model was used to analyze the distribution of comulative soil loss for five storm events, which occurred in the summer of 1981. The output consisted of a map showing erosion or deposition on each 10 x 10 ft subarea at the experimental site. The significant advantage of the model was its ability to predict areal distribution of erosion and deposition. On the average, the predicted results differed from measure erosion and deposition at a point by 25%. Although developed for stripmined and reclaimed areas, the model could be applied to predict erosion and deposition on agricultural watersheds as well as urban watersheds. (Moore-IVI)

BRACKISH-WATER AQUACULTURE IN PYRITE-BEARING TROPICAL SOILS,
Lamont-Doherty Geological Observatory, Palisades, NY.
H. J. Simpson, H. W. Ducklow, B. Deck, and H. J. Cook.
Aquaculture, Vol. 34, No. 3/4, August, 1983. 5 Fig, 5 Tab, 26 Ref.

Descriptors: *Pyrite, *Aquaculture, *Leaching, Tropical regions, Brackish water, Acidity, Oxidation, Iron, Sulfur, Southeast Asia, Malaysia.

Oxidation of pyrite in soils and sediments of coastal areas yields large amounts of acid, as well as soluble iron and aluminum, which seriously reduce yields of aquaculture organisms. Potential for this problem is widespread in tropical and subtropical areas, especially for brackish-water aquaculture in Southeast Asia. Data on water, sediment and soil chemistry at a new aquaculture facility in peninsular Malaysia are reported to document environmental conditions during the initial years of operation when the yields of food organisms are low. Estimated rates of leaching of acid from the pyrite-bearing dike soils suggest that acidity problems will probably persist at this facility for a number of years. Ways to minimize the problems include the fact that extensive soil survey work should be performed prior to site selection and construction of aquaculture facilities. Dike system design should be such that it will minimize soils exposed to the atmosphere. Serious planning as to the acid sensitivity of the potential culture organisms should be made. Systematic collection of water quality data related to acidity impacts should be made on a routine basis to monitor rate and pattern of removal of acidity from the system. (Baker-IVI)

Zeitschrift fur Wasser und Abwasser Forschung Vol. 16, No. 3, p 96-107, 1983. 9 Fig, 3 Tab, 2 Ref.

Descriptors: *Sediments, *Elution, Lake sedi ments, Oxidation, Diffusion, Ammonium, Wate quality.

In slowly running waters or lake bottoms, sediments are formed. Permanent interactions exist between these sediments and the fresh water. The mechanisms of these exchanges are consolidation, diffusion and convection of gas. The processes affect the quality of the sediment and of the overlying water. The concentration of the most reduced substances in the sediment is more intensive than in the body of water. Therefore the interactions between sediments and water lead to a slow elution of the sediments. More than that, the sediment usually has a high demand of oxidizing agents. The elution of aquatic sediments was examined in laboratory scale experiments and generally described by the principals of diffusion. An example of ammonium as verification of experimental results is performed. (Author's abstract)

Descriptors: *Marshes, *Sedimentation, *Accretion, Brackish water, Salt marshes, Louisiana, Barataria Basin.

Vertical accretion and sediment accumulation rates were determined from the distribution of Cs-137 in cores collected from freshwater, intermediate, brackish, and salt marshes in the Barataria Basin, Louisiana. Vertical accretion rates vary from about 1.3 cm/yr in levee areas to 0.7 in backmarshes. Mineral sediment content of the marsh soil profile decreased with distance from the coast. However, vertical accretion rates were about equivalent in areas of the same type. Autochthonous organic

appears to be an important factor defining
cess and rate of vertical accretion, especial-
he freshwater marshes. Except in natural
reas, march accretion rates are less than
nce measured by water level data; however
ne cannot account for observed land-loss
s in the basin area. Management practices
burning and channelization with salt water
n, which may retard the production and
lation of organic matter, have serious con-
es for marsh accretion and land loss.

SEAWATER VS. BRACKISH WATER DESALTING: TECHNOLOGY, OPERATING PROBLEMS AND OVERALL ECONOMICS,
Mekoroth Water Co., Tel Aviv (Israel).
P. Glueckstern, and Y. Kantor.
Desalination, Vol. 44, p 51-60, 1983. 3 Fig, 2 Tab, 7 Ref.

Descriptors: *Desalination, *Seawater, *Brackish water, Reverse osmosis, Membrane processes, Drinking water, Water quaility, Costs, Energy.

Current operation of seawater and brackish water desalting plants is reported and analyzed regarding operating problems and costs. When properly maintained, desalting plants can be considered reliable sources for augmentation of water supply and water quality improvement. Current actual operation costs emphasize the great difference in cost between desalting brackish water by membrane processes and desalting seawater by thermal processes. Quality improvements of drinking water can be very simple and relatively inexpensive. Recent developments in reverse osmosis technology have made brackish water desalting competitive in many cases with conventional water supply. The potential for further development of seawater desalting is still quite large and its realization in due time is very important in order to avoid prohibitive costs for many applications, especially for those with prevailing or projected high energy costs. ONE YEAR OF OPERATION OF ISRAEL DESALINATION ENGINEERING'S MULTI-EFFECT DISTILLATION U.S. VIRGIN ISLANDS,
Israel Desalination Engineering Ltd., Tel-Aviv.
U. Fisher.
Desalination, Vol. 44, p 73-84, 1983. 6 Fig, 2 Ref.

Descriptors: *Desalination plants, *Multi-effect distillation, Drinking water, Virgin Islands, St. Thomas, St. Croix, Scaling.

Three MED (multi-effect distillation) plants for 1.25 MGD were installed in St. Thomas and St. Croix by Israel Desalination Engineering. The Low Temperature MED plants made of horizontal aluminum tubes exceeded the acceptance criteria and continuously supply drinking water to the islands with purity of 16 ppm TDS. Since late 1981 the availability has exceeded 97% and the performance ratio is 12.4 or better. Annual average production was 1.3, 1.3 and 1.27 MGD. The most notable advantages of the MED plants are: the easy start up and operation of the MED process and short period between start up and full capacity; Specific Power Consumption does not change markedly when operating on partial load; low temperature operation results in nearly scale free plant and allows for the use of less expensive construction materials. CAPACITY ADAPTION OF REVERSE OSMOSIS SYSTEMS BY TEMPERATURE AND PRESSURE CONTROL OF THE RAW WATER,
Deutsche Babcock A.G., Krefeld (Germany, F.R.).
K. Heybach.
Desalination, Vol. 44, p 85-90, 1983. 3 Fig, 1 Ref.

Descriptors: *Desalination, *Reverse osmosis, Pressure, Temperature effects, Water treatment.

Permasep Permeator Systems have a permeate capacity variation of nearly three percent for every degree centigrade of temperature variation. The idea of using this temperature phenomenon for the adaption of capacity in permeate production as required over the day originated during the planning stage for three plants of nominal 30 cu m/hr capacity including reverse osmosis system for the production of ultra pure water for electronics. The consumption of permeate subsequently treated to ultra pure quality varied between 30 and 100% of the nominal capacity in the course of the day. The general design of a plant producing ultra pure water is described. The clear and simple relationship between temperature, pressure and feed water, permeate and concentrate flow rates would allow control by microprocessor system and automatically operating valves. This means that there is indeed a capacity adaption for reverse osmosis systems. (Baker-IVI)

DESALTING WATER COSTS USING WASTE HEAT FROM POWER SYSTEMS COMBINED WITH THE VTFE AND VAPOR COMPRESSION,
Ebasco Services, Inc., New York.
S. J. Senatore.
Desalination, Vol. 44, p 129-135, 1983. 2 Fig, 1 Tab, 1 Ref.

Descriptors: *Desalination, *Reverse osmosis, *Multistage flash evaporator, *Vertical tube foaming evaporator, Costs, Energy, Powerplants, Key West, Florida.

An updated desalted water cost comparison is presented for the reverse osmosis (RO), multistage flash evaporator (MSF) and the high efficiency performance vapor compression vertical tube foaming flow evaporator (VCVTFE). The capital costs of the VCVTFE plant is based on a realistic conceptual design for a 2.5 mgd single purpose plant. Together with the vapor compression cycle, high performance ratios of about 35 lbs. product per 1000 Btus can be readily achieved. These high efficiency concepts and use of waste heat are economical with current day high fuel costs. Projected bottom line water costs show that the VCVTFE process is more economical than RO, which is cheaper than MSF desalting costs at today's high energy costs. Power plant turbine exhaust steam normally rejected to the ocean through seawater-cooled condensers, can be used to produce distilled water with an efficient vertical tube foaming flow (VTFE) evaporative condenser. This waste heat VTFE plant was designed to provide 150 cu m per day of distillate having about 5 ppm of total dissolved salts, for use of boiler feed at a 37 MWe coastal power plant at Key West, Florida. The energy cost of the VCVTFE process is only 51% of the energy cost of the RO process. (Moore-IVI)

SEAWATER DESALINATION WITH VERY LOW ENERGY CONSUMPTION,
Bavaria Anlagenbau G.m.b.H., Fuerstenfeldbruck (Germany, F.R.).
L. Cavalieri, and G. Nasser.
Desalination, Vol. 44, p 143-151, 1983. 5 Fig, 3 Tab.

Descriptors: *Desalination apparatus, *Multiple effect process, *Heat exchangers, Vertical tube evaporation, Multi-stage flash evaporation, Corrosion resistance, Scaling, Seawater, Bavaria.

Based on a new plate heat exchanger design, a large scale prototype desalination plant, operating as multiple effect process (vertical tube evaporation (VTE) and multi-stage flash (MSF) process) has been erected in Bavaria. Compact completely welded titanium plate heat exchangers allows the vertical arrangement of 55 stages within a pressure box of 34 m height, 2.5 x 3.2 m ground area, generating a fresh water output of 5000 cu m/day with a Performance Ratio of > 40 (tons of fresh water per ton of supplied steam). A 55 stage VTE evaporator section is combined with a 75 stage MSF section, operating from 130 C down to 30-35 C for maximized steam economy. All heat exchangers are manufactured of titanium while all internal box surfaces in contact with seawater are made of monit, for corrosion resistance. Scaling is minimized as brine is passed once through the plant, and operation with reduced pH values presents no corrosion danger. A large pressure number is feasible in view of the compact heat

exchanger design and the stage interconnecting internal baffle system which avoids external pipework, and due to the automation of the plate heat exchanger manufacturing methods. (Moore-IVI)

SQUEEZING DESALTED WATER COSTS BY PROPER CHOICE OF THE DESALTING TECHNOLOGY AND WATER MANAGEMENT,
National Research Centre, Cairo (Egypt). Pilot Plant Lab.
A. M. Abulnour, M. H. Sorour, F. A. Hammouda, and A. M. Abdel Dayem.
Desalination, Vol. 44, p 189-198, 1983. 3 Fig, 2 Tab, 2 Ref.

Descriptors: *Desalination, *Water reuse, *Costs, Developing countries, Water management, Energy, Water conservation, Social aspects, Egypt.

Due to water shortages in many areas in Egypt, the wider utilization of desalination techniques is certain, but problems may be encountered due to the improper selection of the technological package, or conditions of the site itself. Guidelines for proper selection of the desalting technology are presented which may apply to similar developing countries. Factors which should be considered include: the socio-cultural setting of the community, technical skills in the community, conservation and water management practices, fuel prices, and the importance of incorporating waste disposal and reuse in the same package. The availability of reliable and cheap energy sources may be the most dominant criterion for the selection of a desalting technology. Wider utilization of dual desalination-reuse plants seems to be essential in remote seashore and desert communities. Industries that consume large amounts of energy and water should be discouraged until the time when more energy and water are available from cheap sources. (Moore-IVI)

SPECIFIC ENERGY RECOVERY PUMPING SYSTEM FOR REVERSE OSMOSIS DESALINATION,
Pompes Guinard, Annecy (France).
P. Goubeau, and P. Leroy.
Desalination, Vol. 44, p 199-206, 1983. 2 Fig, 2 Tab.

Descriptors: *Desalination, *Pumps, *Reverse osmosis, Seawater, Mechanical equipment.

The main advantages of reverse osmosis, as opposed to thermal processes, are the lower running costs, especially energy consumption, shorter delivery time, and the low temperature process, and all the energy being in the form of pressure. The problem now is to determine the best energy recovery pumping system: the integrated systems are those offering the greatest advantages in terms of cost savings and operating facilities. The integrated TPMDX energy recovery pumping system was designed by Pompes Guinard, which is one of the largest international pump manufacturers. The TPMDX system has the advantages of reliability, costs, flexibility, and short delivery time. (Baker-IVI)

OPERATING EXPERIENCE AND PERFORMANCE DATA ON AN ADVANCED BARGE-MOUNTED VTE/VC SEAWATER DESALINATION PLANT,
B. Ohlemann, and D. K. Emmermann.
Desalination, Vol. 45, p 39-47, 1983. 5 Fig, 1 Tab, 5 Ref.

Descriptors: *Desalination plants, *Vapor compression, *Vertical tube foam evaporation, *Multistage flash evaporation, MEDA, Helgoland, West Germany.

The floating desalination demonstration plant MEDA presents an advanced concept to produce fresh water from seawater with low energy consumption. This has been achieved by developing a new desalting system with the combination of vapor compression (VC), vertical tube evaporation with foamy upflow (VTFE) and multi-stage flash evaporation (MSF). MEDA was operated at Helgoland in the North-Sea at its design capacity of 5000 cu m/day and a performance ratio of 22 to 1 kg/kg. The 24 VTE effects evaporator combined with two vapor compression topping effects operated at a maximum feed temperature of 135 C with sulfuric acid pretreatment. High heat transfer rates were obtained using foamy upflow in double-fluted evaporator tubes without inter-effect pumps. Data were obtained for an alternative pretreatment system for feed make-up using a fluidized bed ion exchanger system operating in the countercurrent mode. Calcium ion content in the feedwater was demonstrably reduced by more than 90%. The practical feasibility of advanced desalting technology was sucessfully demonstrated. Performance ratios 2 to 3 times higher than MSF process are achievable. The successful demonstration of MEDA at Helgoland supports the acceptance of VC/VTFE or VTFE for single and dual purpose plants. (Moore-IVI)

FLOATING DESALINATION PLANTS; AN ENGINEERING, OPERATING AND ECONOMIC APPRAISAL,
Water and Electricity Dept., Abu Dhabi (United Arab Emirates).
M. Fadel, K. Wangnick, and N. M. Wade.
Desalination, Vol. 45, p 49-63, 1983. 3 Fig, 3 Tab.

Descriptors: *Desalination plants, *Floating desalination plants, *Costs, Construction costs, Barges, Standby plants, Abu Dhabbi.

The simplest type of floating plant consists of a basic pontoon or barge on which the distiller and auxiliary plant are mounted. The obvious attraction of such plants is that practically all construction can be carried out in the country of manufacture. The concept of a self-propelled seagoing plant introduces a large measure of flexibility into the operation of a floating desalination plant. For the relatively small extra costs of propulsion and navigation equipment, such a vessel can carry out several functions, such as: operation as a standby plant; providing reserve capacity to meet exceptional short term demands; and helping to meet rapidly increasing demand until completion of a land based plant. The first fully seagoing desalination vessel, named RUMAITH, is now in service in Abu Dhabi. This vessel carries two 1250 cu m/day MSF distillers and is complete with power generating plant and full marine and navigation facilities. Shore facilities are being engineered and constructed at three remote sites; Silaa, Sir Baniyas Island and Dalma Island. Facilities at each site include water unloading, water storage and pumping, fuel unloading, and fuel pumping. Excluding the shore facilities, the floating plant is shown to marginally lower in cost than a comparable l based plant. The addition of shore facilities permanent fuel and water connections by pipeli and offshore buoys will increase the cost of floating plant to some 7% above the land ba installation. The mobile plant will compete ef tively if regarded as a standby plant for a num of independent on-shore sites. (Moore-IVI)

COMPARATIVE STUDY BETWEEN VAPO COMPRESSION AND MULTI EFFECT BOIL ING DESALINATION SYSTEMS,
King Abdulaziz Univ., Jeddah (Saudi Arabia) Dept. of Thermal Engineering.
M. A. Darwish, K. A. Fathalah, and S. E. Aly.
Desalination, Vol. 45, p 77-80, 1983. 4 Fig.

Descriptors: *Desalination, *Vapor compressio *Multi-effect boiling, Thermodynamics, Costs.

The following arrangements are considered: a multi effect vapor thermocompression (VTC); b multi effect boiling (MEB); c. a hybrid multi-effec boiling/vapor thermocompression. The variation of the thermodynamic properties of water are com puted using special subroutines. Using an ejector t perform the compression of the entrained vapor i considered to be a low efficiency process due t irreversibilities encountered in the entrainment mixing, and compression process. The advantage of using the ejector is that it acts as a controllin device, influenced by the following parameters total temperature difference between the hot and cold ends of the plant, concentration ratio of the brine and its effect on the boiling point elevation, number of effects, temperature difference across the condenser evaporator units. Using ejectors over the same total temperature difference would result in a reduction of the number of effects used in a conventional MEB without a proportional reduction in the plant productivity, which would lead to a reduction in the capital and running costs for pumping power. For specific temperature dif-ference, this arrangement could be beneficial for small capacities since a smaller number of effects would require less maintenance and gives more

characteristics. The hybrid arrangement include the advantages of both MEB and Moore-IVI)

UTER SIMULATIONS OF MULTIPLE- T FFE-VC SYSTEMS FOR WATER DE- ATION,
nst. of Tech. (Sweden). Dept. of Chemical ering.
ation, Vol. 45, p 119-131, 1983. 5 Fig, 4 Ref.

otors: *Desalination apparatus, *Multiple- falling film evaporator, *Vapor compression, tion, Energy, Costs.

nt configurations for multiple-effect falling vaporators (FFE) and vapor compression ystems were simulated. For multiple-effect ystems, the number of effects were varied to 21. For VC systems, different locations compressor were studied. A plant with a y of 6790 cu m/day (1 MGD) was chosen. g surface of evaporators and preheaters, temperature, temperature difference in each tube length and liquid load are process eters which were investigated. Performance for the multiple-effect FFE configurations l to be low, which may be due to the use of n tubes in these simulations. The 15 effect uration had the minimum water cost. For C systems, the economy of size is very im- t in designing a feasible system. Of the three onfigurations, the configuration with the essor operating across one FFE effect shows tly lower unit water cost. For a capacity of D, and optimum evaporation area of 4500 sq ngle stage centrifugal compressor operating i = 1.19 and a total energy requirement of W will be needed. Sensitivity analyses show or energy conservation, the highest brine rature should approach 120 C and the evapo- with an optimum tube length of 7 m, should erated at a high liquid load. (Moore-IVI)

ATING EXPERIENCE OF DESALINA- UNITS IN SCHEVCHENKO,
Baranov, N. A. Kabluchko, P. K. Lebedev, Samarkin, and A. P. Egorov.
Desalination, Vol. 45, p 167-174, 1983. 5 Ref.

Descriptors: *Desalination plants, *Shevchenko, USSR, Nuclear powerplants, Seawater, Potable water, Feedwater.

Shevchenko is the only town in the USSR using only artificially prepared potable water, the main component of which is distillate produced from seawater. Desalination units of three types have been built in Schevchenko and operated at the atomic thermoelectric fast reactor plant. Four and five stage concurrent units with natural circulation of solution had a limited number of evaporation stages because of the necessity of ensuring a temperature drop of no less than 10-12 C per stage for normal operation. At start-up, the units are inert, and a long time is needed to produce stable conditions. The 10-stage concurrent unit with forced brine circulation is more economical in heat consumption, and has good stability and smooth operation. The distillate produced can be used to feed steam generators of electric power stations without additional treatment. The 34-stage flash unit is easy to operate, compact and similar to the 10-stage unit in heat consumption. It is very sensitive to environmental disturbances, and the distillate produced is not applicable to feed steam generators. It is not compatible with scale prevention by means of seed crystals. The 34-stage unit has a narrow range of possible output variation, 80-100%. The 10-stage evaporation units have been chosen to extend the Shevchenko desalination complex. They are reliable in operation and give a distillate of 0.5-2.0 mg/l salt content. (Moore-IVI)

RELIABILITY ASSURANCE SURVEY - AN INITIAL STEP TOWARDS INCREASED OPERATING RELIABILITY AT EXISTING DESALINATION FACILITIES,
Kuljian Corp., Melbourne, FL. Desalination Div.
R. E. Bailie.
Desalination, Vol. 45, p 185-194, 1983. 1 Fig, 3 Tab, 7 Ref.

Descriptors: *Desalination plants, *Maintenance, *Computers, *Reliability, Middle-East, Statistical methods, Planning.

Over the next few years a large number of new MSF units will be added to the current installed capacity of desalination facilities in the Middle-East. There will be an ever increasing need to achieve optimum utilization of the maintenance personnel while insuring the operating reliability of these facilities over the long term. The Reliability Assurance Survey offers a step-by-step procedure which utilizes proven reliability engineering methods to initially evaluate and later predict the reliability of all critical subsystems and components within an existing facility. The procedure begins with the collection and analysis of historical data to develop a data base, followed by a computerized manipulation of this data to define the most critical subsystems and components. Systematic methods and statistical techniques are utilized to predict the reliability of these critical subsystems and components. With the aid of a microcomputer system, the data base can be continuously up-dated and the maintenance planning staff can be provided with sufficient information to predict the reliability or failure of all critical subsystems and components. A criticality analysis can focus upon those most critical components which may be candidates for a condition-based maintenance program which would use on-line diagnostics to continuously monitor the condition of the major down-time sources. PARAMETRIC STUDY ON SEAWATER REVERSE OSMOSIS DESALTING PLANTS,
Bechtel National, Inc., San Francisco, CA. Research and Engineering.
R. Soo-Hoo, L. Awerbuch, S. May, M. Mattson, and S. Kremen.
Desalination, Vol. 46, p 3-15, 1983. 9 Tab, 1 Ref.

Descriptors: *Desalination, *Reverse osmosis, Membrane processes, Seawater, Cost analysis, Automation, Energy recovery, Intakes, Site selection.

A comprehensive parametric technical and economic study of seawater reverse osmosis desalination plants was undertaken. The objective was to derive updated costs for plants ranging from 100,000 gpd to 5 million gpd at a Caribbean site and at a continental US site. The study considered hollow-fiber and spiral-wound membranes in one- and two-pass configurations, various seawater intakes (surface, seawater well, Panney collectors), various high pressure pumping systems (centrifugal, positive displacement), optional energy recovery systems (Pelton wheel, hydroturbines, workflow exchangers), and operation and maintenance labor requirements. Other variables included in the study were reduced operating pressure, extended membrane life, higher recovery ratio, improved pumping and energy recovery system efficiency, and increased plant automation. To obtain the lowest cost product water in seawater reverse osmosis, one of the key decisions in the RO plant design is the selection of the site and the intake system suitable for the local hydrogeology of that site. Intake selection is important because of its impact on the degree of pretreatment required for proper plant operation and the resulting product water economics. (Baker-IVI)

DESALINATION OF WATER IN SAUDI ARABIA BY REVERSE OSMOSIS, PERFORMANCE STUDY,
University of Petroleum and Minerals, Dhahran (Saudi Arabia).
C. K. Wojcik.
Desalination, Vol. 46, p 17-34, 1983. 6 Fig, 5 Tab, 3 Ref.

Descriptors: *Desalination, *Reverse osmosis, Saudi Arabia, Salbukh, Buwayb, Jeddah, Maintenance, Performance evaluation, Costs, Salinity, Seawater.

The performance of major reverse osmosis plants in Saudi Arabia is reviewed in terms of their actual productions, maintenance problems, water recoveries, quality of products and their cost. The operating experiences with these plants have ranged from marginal to excellent. Most of the problems encountered were related to the following concerns, either singly or in combination: harsh conditions in which these plants had to operate, inadequate pretreatment of water, lack of trained operators, lack of preventive maintenance, as well as designs that did not take into consideration these factors. The plants discussed were at Salbukh, Buwayb, and Jeddah. Whether the process with present membrane technology can be successful in desalination of Saudi Arabia's seawaters still remains an open question. Thus far such experience has been limited to the Red Sea where salinity rarely exceeds 42,000 ppm. (Baker-IVI)

DESALINATION BY REVERSE OSMOSIS IN CHINA,
W. Ying.
Desalination, Vol. 46, p 35-40, 1983. 8 Fig, 1 Ref.

Descriptors: *Desalination, *Reverse osmosis, *China, Water reuse, Water supply development, Membranes.

Research is described concerning desalination by reverse osmosis (RO) and water reuse in China. RO desalination research began in China in 1967 with the first ten years being devoted to translation of foreign papers on the subject into Chinese. From 1977-1980 rapid progress was made in the area of membrane research. Two kinds of aromatic polyamide hollow fiber and a kind of honeycomb dynamic formed membrane module and desalination equipment were developed. In recent work much of the emphasis has been aimed at solving RO theoretical questions and problems that arise during practical application of the technique. Problems currently being researched include the development of materials for membranes for special purposes, development of chemical products, and shortening of the cycle of production. Steps are being taken to increase the testing period of RO

service life before producing the equipment, to select good plants for manufacturing RO equipment, to pay great attention to the equipment used in the pretreatment process and increase the investment for pretreatment to 1/4 to 1/3 of the total budget, and to train accomplished operators. EXPERIENCE WITH DESALINATION OF SEA AND BRACKISH WATER USING MINIMUM PRETREATMENT AND HIGH TEMPERATURE,
Danske Sukkerfabrikker, Nakskov. Reverse Osmosis Div.
W. K. Nielsen.
Desalination, Vol. 46, p 67-79, 1983. 6 Fig, 6 Tab, 8 Ref.

Descriptors: *Desalination, *Membranes, Membrane processes, Seawater, Brackish water, Reverse osmosis, Costs.

In 1980 a new thin film composite membrane was introduced. This membrane can operate at high temperatures in the range of 0-80 C. Cleaning can be performed with acid and alkaline chemicals in a pH range of 1-12.5. The HR95/98 membranes in the plate-and-frame configuration give a combination which has proven to be extremely dependable. Multi-media filtration and security screens are frequently satisfactory as pre-treatment. Depending on the composition of the water, chemical additions are reduced compared to conventional reverse osmosis operation. The plants are designed as continuous plants with recirculation which has proved to give high security of operation and a high degree of flexibility in operating range. Compared to desalination with cellulose acetate membranes the new technology offers several advantages amongst which membrane stability, plant security against failures, reduce chemical and pretreatment costs and safe operation are the most predominant. (Author's abstract)

TEST RESULTS ON FT-30 EIGHT-INCH-DIAMETER SEAWATER AND BRACKISH WATER REVERSE OSMOSIS ELEMENTS,
FilmTec Corp., Minneapolis, MN.
R. E. Larson, R. J. Peterson, and P. K. Eriksson.
Desalination, Vol. 46, p 81-90, 1983. 4 Fig, 11 Ref.

Descriptors: *Desalination, *Reverse osmosis, Membrane processes, Seawater, Brackish water, Membranes.

Spiral-wound reverse osmosis elements formed of FT-30 membrane have been used for a variety of desalting applications around the world. The membrane was originally developed to satisfy the requirement for a true single-pass seawater membrane that would maintain its salt rejection characteristics while operating in a variety of seawater feeds. Later test results proved its applicability as a brackish-water desalting membrane as well, and FT-30 elements are now operating over a broad spectrum of feedwaters, ranging from tapwater to difficult industrial separations. The FT-30 membrane is noncellulosic and is of a thin-film composite configuration. It satisfies the main requirement of having high flux and excellent salt rejection, but in addition it is chemically stable, can operate over a broad range of pH, is partially resistant to chlorine exposure and shows good stability at high feedwater temperatures. These latter characteristics facilitate both acid and caustic cleaning, an important consideration under fouling conditions. Considerable field application experience has been obtained with FT-30 membrane elements over the past three years. This experience has given excellent results, although it has been limited to small elements - the largest manufactured by FilmTec until recently was 4 x 21 inches and gave 600 gpd on seawater and 1200 gpd on brackish water. In early 1982 4 x 40-inch elements began to be produced and used commercially. Then in the summer of 1982, 8 x 40-inch elements were manufactured for the first time, meeting the design goals of single-pass seawater performance with product flows of over 5,000 gpd, and under brackish water conditions with flows of over 10,000 gpd. These large elements are now being tested on seawater and brackish water feeds in the Mid-East, in England, in Florida, and in several other locations. Single-pass seawater performance data and brackish-water test results are presented. Eight-inch elements are now being produced in commercial quantities for use in large reverse osmosis installations. (Author's abstract)

ULTRAFILTRATION MEMBRANE PROCESSES - THE SLEEPING GIANT,
RQ Associates, Inc., Teaneck, NJ.
R. M. Quinn.
Desalination, Vol. 46, p 113-123, 1983. 9 Fig.

Descriptors: *Desalination, *Membrane processes, Ultrafiltration, Filters.

Ultrafiltration processes and systems are reviewed and evaluated. Hollow fiber, spiral wound, and tubular systems and their relative process and cost advantages are reviewed. The effects of process parameters such as foulants in feed water, temperature, operating pressure and flux on process design and system configuration are considered. The paper can serve as an introduction to ultrafiltration for those who are not yet familiar with the technology. The ability of current membranes to treat a variety of streams, and the need for purer products and more effective concentration/separation processes are creating a renewed interest in the field. (Baker-IVI)

DESALINATION OF HIGH SALINITY SEA WATER BY REVERSE OSMOSIS (SUMMARY),
Water Reuse Promotion Centre, Tokyo (Japan).
Y. Kunisada, K. Okada, M. Tsureish, K. Kikuchi, and M. Hirai.
Desalination, Vol. 46, p 145-150, 1983. 2 Fig.

Descriptors: *Desalination, *Seawater, *Reverse osmosis, Water temperature, Salinity.

Performance tests were carried out on three new reverse osmosis modules for single pass desalination of high salinity and high temperature seawater, developed by Japanese manufacturers. Experiments were carried out on HR5350S module under the conditions of feed water salinity 42,000 mg/l, feed water temperature 40 degrees C, operating pressure 54 kg/sq cm and recovery ratio 30% for 3,000 hours, on SP-210 module under the conditions of feed water salinity 42,000 or 50,000 mg/l, feed water temperature 35 or 40 degrees C, operating pressure 56 or 63 kg/sq cm and recovery ratio 35-25% for 4,260 hours and on SP-110X module under the conditions of feed water salinity 50,000 or 55,000 mg/l, feed water temperature 30 or 35 degrees C, operating pressure 63 kg/sq cm and recovery ratio 25-21% for 1,640 hours. TDS of the product water were about 200 mg/l, less than 200 or about 250 mg/l and 210-220 mg/l respectively. Each module showed stable performance. (Author's abstract)

SOLUTION OF CONTRADICTORY PROBLEM OF SIMULTANEOUS DESALINATION AND CONCENTRATION IN REVERSED OSMOSIS,
C. A. Yagodin, B. F. Nikolsky, N. F. Kuleshov, and A. A. Svitsov.
Desalination, Vol. 46, p 171-177, 1983. 3 Ref.

Descriptors: *Desalination, *Reverse osmosis, Sea water, Brines, Water supply, Desalination wastes.

The optimum relation must be established between the volumes of water and brine, when the reverse osmosis process is used to desalinate and purify water. A method of calculation of the optimum relation for reverse osmosis units takes into account the inconsistency of the task of simultaneous desalination and concentration of salt solutions. In testing the procedure it was determined that the method permitted a reduction in the volume of wastes discharged from reversed osmosis units to the environment. By developing the flow sheets of reverse osmosis units using the derived depen cies it was possible to calculate the cross secti area of the membrane apparatus along the path solution being separated. It was possible to ca late the capacity and quality of permeate in section, the degree of concentrating in the w unit and its individual parts. (Baker-IVI)

ADSORPTION - DESORPTION STACK FO CYCLIC ELECTRODIALYSIS IN OPE SYSTEM,
M. E. Abu Goukh, and D. W. Thompson.
Desalination, Vol. 46, p 211-223, 1983. 8 Fig, Tab, 9 Ref.

Descriptors: *Desalination, *Electrodialysis, Sca ing, Membrane processes, Cyclic electrodialysis Scaling.

The main problems encountered in conventiona electrodialysis, ED, are reviewed. Cyclic electro dialysis is proposed as an attractive alternativ with ability to circumvent the main problems i the standard unidirectional process; namely, th scale formation and membrane fouling. The mai design and operation features of cyclic electrodia lysis are discussed and compared with those o conventional electrodialysis. Design and operatin features of an adsorption-desorption stack which i suitable for cyclic electrodialysis are presented Stack capability has been demonstrated using aque ous sodium chloride solution under different oper ating conditions of feed concentration, production rate, applied voltage, cycle timing and demineraliz ing path length. A separation factor as high as 65 was obtained in an open system, while separation factors of the order 1000 had been obtained in a closed system. (Author's abstract)

CHARACTERISTICS OF FLOW AND MASS TRANSFER RATE IN AN ELECTRODIA-LYZER COMPARTMENT INCLUDING SPACER,
Hitachi Research Lab., Ibaraki (Japan).
O. Kuroda, S. Takahashi, and M. Nomura.
Desalination, Vol. 46, p 225-232, 1983. 11 Fig, 5 Ref.

Descriptors: *Membrane processes, *Desalination, *Ion exchange, Mass transfer, Flow rate, Electrodialysis.

In order to determine the optimum compartment structure and operation conditions for electrodialy-

e hydraulic characteristics and mass transfer
ting ability of net-type (mesh) spaces insert-
a compartment were investigated. The rela-
etween spacer structure and these two char-
tics were examined in experiments through
ctrochemical reaction of the redox system.
en the fluid friction coefficient and Reynolds
r the relation was established with channel
ls, the gaps between spaces and channel
and mesh size. Mass transfer promotion
teristics were measured electrochemically.
pacers with larger mesh showed a higher
tion effect at relatively low pressure loss for
nt channel intervals. This demonstrated that
effective spacers could be developed by ad-
the mesh sizes. Temperature variation of
ransfer coefficients obtained coincided with
rature variations of the limiting current den-
r electrodialysis. (Baker-IVI)

ranes, Membrane processes, Reverse osmo-
ater transport, Permeability coefficient, Hy-
is.

ose acetate membranes undergo hydrolytic
position which is accelerated at very high or
H levels. Hydrolysis results in the loss of
groups leading to a sharp decline in mem-
performance. Minimum hydrolysis rates
in the pH range of 4-6. The two parameter
ort equation gives salt and water permeabil-
fficients which depend on membrane acetyl
t. In this paper both coefficients, calculated
erformance changes are shown, to increase
entially with time. Rate constants calculated
hese changes show changes in salt perme-
to be an order of magnitude greater than
es in water permeability. The observed dis-
cy in salt and water transport kinetics sug-
iffering mechanisms for these two processes.
ntly, salt-water coupling during transport in-
s as membrane hydrolysis progresses. Thus,
vo parameter transport equations do not
since they neglect the salt-water coupling
menon. The use of other membrane trans-
nodels to account for changes in membrane
mance as hydrolysis occurs is discussed. The
n between acetyl content and hydrolysis
also considered. (Baker-IVI)

**LINATION PLANT PROGRAM TO
E SHORTAGE OF WATER IN THE
HERN ITALIAN ISLANDS (SICILY),**
per il Mezzogiorno, Rome (Italy).
nsiglio, and M. Creton.
nation, Vol. 45, p 209-220, 1983. 8 Tab.

iptors: *Desalination plants, *Management,
Italy, Water supply, Contracts.

iginal form of contract is presented which
les a single call for tenders for installing six
nation plants in some small islands of Sicily
nds the contractor to the possible operation
the plants concerned for an eleven year
. The use of water desalination plants is the
method of supplying enough water for sev-
f the small Sicilian islands. The main choices
in implementing the desalination plant pro-
consist of entrusting the contractor with the
ion of the desalination plant for a consider-
ng time of up to 11 years, arranging a single
covering all the desalination plants on a
ey basis, or giving the companies the choice
ect the kind of desalination processes. Once
nder has been established, the goals of the
were set as follows: comprehensive bids for
, supply and installation of six desalination
, with relative power generating stations and
civil works; comprehensive bids for the operation of all the plants and auxiliaries for the first year following acceptance of the plant; and the committment to operate the desalination plants and auxiliaries for a further 10 year period with coverage of any expenditure needed for maintenance and operation. DESIGN AND PERFORMANCE OF THE WORLD'S LARGEST OPERATING DUAL-PURPOSE SEA WATER DESALTING PLANT,
INCON Anlagentechnik G.m.b.H., Homburg/Saar (Germany, F.R.).
F. G. Abbosh, I. Kamal, S. Chalchal, and H. Gerke.
Desalination, Vol. 45, p 223-230, 1983. 2 Fig, 2 Tab.

Descriptors: *Desalination, *Water treatment facilities, Water supply development, Water shortage, Saudi Arabia, Jeddah, Scaling, Corrosion, Powerplants, Chlorination, Control systems, Seawater.

The 500 MWe/220,000 cu m/day Jeddah 4 Power and Desalination Plant is the largest operating dual-purpose plant in the world. It was needed in Saudi Arabia to meet the growing water and power requirements of the Jeddah area. The plant is based on 5 boilers and turbogenerator sets, each producing 100 MW net electrical power. A novel feature of Jeddah 4 is its sophisticated instrumentation, control and computer system which provides for complete central operation and control from the main control room. All these systems are designed for fail-safe operation, and plant availability is assured by provision of manual control back-up for all major plant items. Owing to adequate control of tube-fouling and low non-equilibrium losses, performance ratios are 10 to 20% better than design. Production levels are 10% above design, with steam consumption below the design values. Scale control has been based on dosing with sulfuric acid at less than the stoichiometric amount, leaving a residual alkalinity of about 10 ppm in the make-up feed. The seawater feed to the Jeddah 4 plant is continuously dosed with chlorine at a rate of 2 ppm. During early stages of operation a gradual loss in vacuum was observed after the 4 stage ejector/barometric condenser system had been in operation of 6-10 hours. External and internal corrosion of stainless steel pipes, aggravated by the aggressive ambient atmosphere and possible contact with stagnant sea water was noted and corrected. (Baker-IVI)

THERMAL DESALINATION OF SEA WATER IN THIN FILM PLANTS,
Dalnevostochnyi Politekhnicheskii Inst., Vladivostok (USSR).
V. N. Slesarenko.
Desalination, Vol. 45, p 295-302, 1983. 4 Fig, 6 Ref.

Descriptors: *Desalination plants, *Seawater, *Thin films, Heat exchangers, Hydrodynamics, Desalination, Entrainment, Scaling.

A further improvement of desalination plants calls for finding new ways on intensification of their working process. This can be achieved by using heat exchangers with thin film liquid supply in the flow sheet of a plant, the apparatus being characterized by a high-efficiency heat exchange. Hydrodynamics and heat exchange were investigated in desalination plants in which a liquid is fed to the heating surface due to rising entrainment of film by a hot air flow and free washing of a horizontal surface. The intensity of heat exchange in horizontal and rising film heat exchangers are 2-3 times higher than in the other types of desalination plants. Temperature differences are rather low, which prevents scale formation on the heating surface. The coefficients for sea water are 15-20% higher than those for distillate, confirming the conclusion about the impossibility of using data obtained on distillate and single component brines in design methods. (Baker-IVI)

INVESTIGATION OF WATER DESALINATION BY DISTILLATION TECHNIQUE,
N. M. Sinev, V. G. Shatsillo, V. B. Chernozobov, A. A. Samarkin, and Ju. S. Baranov.
Desalination, Vol. 45, p 315-320, 1983. 1 Tab.

Descriptors: *Desalination, *Distillation, Evaporation, Scaling, Corrosion control, Shevchenko, USSR.

The main large stationary desalination units of different types developed in the USSR and used in the design of the largest plant in Shevchenko having the output of 100000 cu m/day of distillate is described. The plant operates in close interrelation with an atomic thermoelectric 5H-350 fast reactor plant and back pressure turbines. Some results of constantly performed studies into heat transfer, vapor separation, control of scale deposits and corrosion are discussed along with results of searching for new thermal systems and instruments to be used for the improvement of operating distillation desalination units and the development of new ones. Further prospects of thermal desalination are associated with the use of multi-stage units equipped with horizontally arranged tube film evaporators. (Author's abstract)

DESALINATION PLANT CONTROL WITH MICROPROCESSOR BASED DIGITAL TECHNOLOGY,
Honeywell Europe S.A., Brussels (Belgium). Process Management Systems.
G. O. Hultin, and R. Harper.
Desalination, Vol. 45, p 329-336, 1983. 4 Fig, 1 Ref.

Descriptors: *Desalination plants, *Corrosion control, *Digital computers, Microprocessors, Computers, Automation.

The success of improved control strategies for minimizing corrosion and for improving plant operation efficiency is dependent on the data acquired from the process. To obtain improvements in control, more data than is now generally available will have to be collected. Distributed microprocessor based digital technology with a hierarchical system approach provides effective tools for on-line corrosion control by making use of the available historization, trending and alarming features. The hierarchical system structure facilitates improved production efficiency at different levels of sophistication, from a basic control concept to an automatically optimized operation by making use of thermodynamical steam and water properties. A high level of reliability is reached through this system structure, making costly solutions with redundant computers unnecessary. (Author's abstract)

RECENT SOLAR DISTILLATION DEVELOPMENTS,
A. Delyannis, and E. Delyannis.
Desalination, Vol. 45, p 361-369, 1983. 7 Fig, 1 Tab, 13 Ref.

Descriptors: *Desalination, *Water supply, *Solar distillation, SOLERAS Project, Potable water, Distillation, Rain, Wind energy, Arid areas.

In arid areas rain is often collected and stored to be used as fresh water supply over the year. Solar distillation may provide potable water for remote locations where other water supply systems are not available. Since the intensity of solar radiation per unit of evaporating area is determined by nature, the output of a solar distillation unit in a given location can only be increased by increasing the evaporating surface. Solar distillation can never be a steady operation due to changes in intensity of the sun during the day. There are two ways of increasing the fresh water yield in connection with standard greenhouse distillation units. The first is rain collection. The second way of increasing the efficiency of conventional greenhouse type solar stills is to use preheated water or waste hot water as the feed. Use of more effective desalination

processes of proven technology, instead of conventional greenhouse type solar distillers, results in higher efficiencies. Direct or indirect utilization of solar energy may also be combined with other desalination processes, without necessarily having the production of hot water as intermediate stage. Wind energy to produce electricity or photovoltaics may be combined with reverse osmosis or electrodialysis. (Baker-IVI)

DESALINATED WATER PRODUCTION AT LNG-TERMINALS,
Nuovo Pignone S.p.A., Florence (Italy).
A. Antonelli.
Desalination, Vol. 45, p 383-390, 1983. 2 Fig.

Descriptors: *Desalination, *Fuels, *Liquefied natural gas, Natural gas, Sea water, Thermodynamics, Freezing.

A process has been worked out to apply the laws of thermodynamics to sea water desalination making use of liquefied natural gas (LNG). Ambient temperature heat is applied to LNG which evaporates and generates power. This power is employed to extract heat from sea water, part of the sea water is frozen and the heat is discharged to the environment. The ice produced is melted at ambient temperature and desalted water is obtained. Conventional technology is used for every component of a plant using this method. This type of plant may produce quite a substantial amount of desalted water, up to 3.2 tons of water per ton of LNG. Therefore a terminal capacity of 5,100,000,000 NM3/yr of natural gas may produce 10,000 t/d of water, equivalent to the needs of a town of 40,000 inhabitants. (Baker-IVI)

REVERSE OSMOSIS MEMBRANE SENSITIVITY TO OZONE AND HALOGEN DISINFECTANTS,
California Univ., Los Angeles. Dept. of Chemical, Nuclear, and Thermal Engineering.
J. Glater, M. R. Zachariah, S. B. McCray, and J. W. McCutchan.
Desalination, Vol. 48, p 1-16, 1983. 10 Fig, 3 Tab, 13 Ref.

Descriptors: *Desalination, *Reverse osmosis, *Disinfectants, Membranes, Ozone, Chlorine, Iodine, Cellulose acetate membranes, Polyamides, Bromine, Hydrogen ion concentration.

The sensitivity of commercial reverse osmosis membranes toward halogen and ozone disinfectants has been measured at carefully controlled concentration and pH levels. Membrane sensitivity varies with polymer type, disinfectant chemical, and solution pH. Aromatic polyamide membranes are damaged by halogen addition to aromatic rings within the polymer. This process follows predictable reaction kinetics. Polymer viscosity changes with increasing membrane damage have also been followed. Cellulose acetate membranes are generally resistant to halogens and halogen derivatives. Polyamide type membranes are sensitive to chlorine and bromine but show reasonable resistance with appropriate pH control. Ozone will damage any membrane tested, but cellulose acetate shows some resistance at low pH levels. This type of membrane may resist low concentrations in systems designed for ozone disinfection. All membranes are generally resistant to iodine. Polyamide type membranes are generally resistant to chlorine dioxide at near neutral pH. This chemical evidently attacks membranes at high pH by oxidation since no halogen uptake is noted. DuPont B-9 membrane chemically combines with chlorine during exposure. This process is accompanied by decreasing viscosity of polymer solutions in dimethyl sulfoxide. Chlorine uptake data follows pseudo-first reaction kinetics. (Baker-IVI)

SHORT CUT DESIGN METHODS FOR REVERSE OSMOSIS SEPARATION WITH TUBULAR MODULES,
Stevens Inst. of Tech., Hoboken, NJ. Dept. of Chemistry and Chemical Engineering.
K. K. Sirkar, and G. H. Rao.
Desalination, Vol. 48, p 25-42, 1983. 2 Tab, 14 Ref.

Descriptors: *Desalination, *Reverse osmosis, Turbulent flow, Mathematical equations.

The basis for obtaining explicit flux expressions in reverse osmosis separations with concentration polarization has been illustrated for tubular modules with turbulent flow. Various analytical equations developed thereby to predict the required number of tubes and the permeate solute concentrations are described and compared with one another as well as with the currently used numerical methods. The utility of such simple design procedures are pointed out. The possibilities and difficulties of adopting these procedures for designing spiral-wound modules have been discussed. The analytical equations can be adopted to 'tapered-flow' reverse osmosis without much difficulty. (Author's abstract)

POLYPIPERAZINAMIDES: NEW POLYMERS USEFUL FOR MEMBRANE PROCESSES,
Istituto Guido Danegani S.p.A., Novara (Italy).
P. Parrini.
Desalination, Vol. 48, p 67-78, 1983. 14 Fig, 5 Ref.

Descriptors: *Desalination, *Membranes, Membrane processes, Polypiperazinamides, Polymers.

A class of polymers based on piperazinamides is described. The structures and physical properties of main polymers are compared and the osmotic performance is examined. Among the polymers considered, the trans-2,5-dimethylpiperazinthiofurazan 3,4-amide was developed as a precursor for reverse osmosis. The osmotic properties of asymmetric membranes obtained from TFZ amides are reported. The resistance to temperature, to variations in pH and to chlorine and its derivatives are of great interest. This type of membrane assembled in different modules, is used in the desalination field as well as in other technological processes such as fluid treatment, the oenological field, and materials recovery. At present, 50 to 100 cm wide polypiperazinamide membranes are produced commercially. They are prepared on textile supports, so as to make their utilization in preparing spiral modules easier. PREVENTION OF CALCIUM SULFATE SCALE DEPOSITION BY A FLUIDIZED BED,
Technische Hogeschool, Delft (Netherlands). Dept. of Chemical Engineering and Chemistry.
J. A. M. Meijer.
Desalination, Vol. 47, p 3-15, 1983. 12 Fig, 15 Ref.

Descriptors: *Desalination, *Distillation, *Fluidized beds, *Scaling, Calcium sulfate, Seawater, Brackish water, Fouling, Evaporators, Hemihydrate, Anhydrite.

The scale inhibiting capability of a fluidized bed in the vertical heat exchanger tubes of a Multi Stage Flash/Fluidized Bed Evaporator (MSF/FBE) was investigated. The MSF/FBE is a vertical flash evaporator used for the distillation method of converting sea and brackish water into fresh water. This method possesses excellent features with respect to investment costs, specific heat consumption and prevention of fouling and scaling. The temperatures at which calcium sulfate scale starts to deposit despite the abrasive action exerted on the wall by fluidized bed particles was determined. In all experiments the calcium sulfate hemihydrate solubility line could be exceeded to a certain extent without scale deposition. At concentration factors of sea water larger than 2.5 hemihydrate was found, while at lower concentrations factors anhydrite was deposited. The highest top temperatures were reached when the brine was deaerated and recirculation of seeding crystals was excluded. Scale deposition is prevented more efficiently by 2 or 3 mm glass particles than by 1 mm glass particles. A model is given to describe the competitive processes of scaling and abrasion at the wall of the heat exchanger tubes. Both processes were studied separately. The removal rate of calcium sul crystals were determined by abrasion tests experiments in a scaled up fluidized bed, and growth rate of calcium sulfate by experiments high temperature rotating disc reactor. A new antiscale product, Nalco 8599-NI, w tested for its effectiveness in a sea water evapo tor located in the South-East end of the Ara peninsula, operating with Gulf water. The inhi tor incorporates a specific dispersant agent, is s plied in liquid form and is miscible with sea-, fre or distilled water at any proportion. Nalco 8599-I is effective as regards growth of both crystalli tion nuclei and pre-existing crystals in that double layer of electrical charges is created. In t first case, a distortion of the crystallograph growth plans occurs and the growth of the micr crystal is inhibited. In the second case, the doub electric layer has a dispersant action and the cry tal, therefore, will no longer originate scale. T altered structure and the strong dispersive acti allow the particles to be easily transported fro the system at normal flow rates. The Nalco 859 NI proved effective at 7 ppm at a brine temper ture of up to 110 degrees C. The product was al shown effective at 5-6 ppm for the same temper ture level. Lower dosages may be used when th top temperature of the brine is less than 110 d grees C. (Baker-IVI)

Descriptors: *Desalination, *Scaling, Distillation Corrosion control, Additives, Temperature.

Trials were conducted using commercially avail able high temperature threshold additives with packaged vapor compression distiller to study the performance of these chemical in distillation plants which operate with boiling brine in contact with heat transfer surfaces at elevated temperatures. The vapor compression distiller uses vertical fluted tubes in an upflow natural circulation mode and operates just above atmospheric pressure. Some of the chemicals tried are those which have enabled a number of large MSF distillers to operate for thousands of hours between cleanings at terminal temperatures of over 100 C. Improvements made in chemical treatment as part of the test program have resulted in extending the time period between cleanings five fold. It is believed that these improvements can be used to make threshold type scale inhibition a practical reality in large scale high temperature multi-effect and vapor compression distillers as well as many MSF plants which have not responded favorably to conventional high temperature additives. llation plants, operating at least partially well
e ambient temperature, must be protected
st scaling. In principle, this can be achieved
number of different processes - eight of which
xamined and assessed. These studied included
ive dosing, acid dosing, lime magnesium car-
te-process, thermal precipitation, cation ex-
ge, seeding processes, coated or polished sur-
on line mechanical cleansing and additive
g. According to a cost-benefit analysis ion
nge seems to be an interesting alternative to
ve dosing. The comparison between fixed
nd moving bed ion exchange in the range of
ities between 200 and 20000 t/d distillate
tes that moving bed ion exchange is less
taneous than a fixed bed process. This state-
is particularly valid for small and medium-
plants. At present more information is needed
rning service life time, the rate of resin-
ction within the recirculating pumps of the
g bed process, and the rate of resin-destruc-
e osmotic shock in the fixed bed process. It is
sted that a reduction of about 10% of the
ic water cost is possible if the feed of a single
se MSF plant is treated by ion exchange
d of additive dosing. It must be emphasized,
ver, that a possible reduction of this 10% is
y of the same order as the range of accuracy
cost estimate. As energy prices increase, the
on will shift in favor of the ion exchange
ss. (Baker-IVI)

RO DESALTING OF BRACKISH WATER OVERSATURATED WITH CASO4,
Mekoroth Water Co., Tel Aviv (Israel).
M. Wilf, and J. Ricklis.
Desalination, Vol. 47, p 209-219, 1983. 3 Fig, 1 Tab, 9 Ref.

Descriptors: *Desalination, *Reverse osmosis, Brackish water, Salinity, Calcium sulfate, Cost analysis, Financial aspects.

The possibility of recovery increase in the commercial reverse osmosis plant, desalting brackish feed of 5000 ppm total dissolved solids salinity, was tested in a pilot plant equipped with 4 inch spiral wound and hollow fiber modules. The plant desalted the reject stream from the commercial plant. Long term field tests of up to 4000 hr on membrane performance were conducted. During the tests the ratio of the calcium and sulfate ion concentrations product to the formal solubilities of calcium sulfate at the corresponding ionic strength was maintained in the range of 1.2 to 2.3. Stable membrane performances were obtained with respect to productivity and salt rejection. Based on the field results a 900 cu m/d unit for reject desalting was constructed. The unit enabled an increase of the product recovery in the commercial plant to 65% from a design value of 53%. Difficulties which had been encountered in earlier long term tests such as feed component depletion and foulant accumulation during the test period were avoided by the once through flow of the feed in the experimental system. The stable performance of the membranes indicated that it would be possible to operate the commercial reverse elements at much higher concentrations of sparingly soluble salts that the safe limits accepted thus far. A substantial margin exists which can be exploited for better desalting economics. (Baker-IVI)

CONTROL OF BIOLOGICAL FOULING IN SEAWATER REVERSE OSMOSIS DESALINATION,
Fairleigh Dickinson Univ., Teaneck, NJ. Dept. of Biological Sciences.
H. Winters, I. Isquith, W. A. Arthur, and A. Mindler.
Desalination, Vol. 47, p 233-238, 1983. 7 Ref.

Descriptors: *Desalination, *Reverse osmosis, *Membrane processes, Scaling, Microorganisms, Chlorination, Ferrous sulfate, Citric acid, Tannic acid, Polyacrylate, Seawater.

Various non-acid pretreatment schemes were studied in a seawater reverse osmosis desalination plant for one year. Particular attention was given to microbial aspects of fouling. Four different approaches to non-acid pretreatment were considered: chlorine starvation by the use of minimal chlorine which just satisfied the chlorine demand of the seawater coupled with ferrous sulfate coagulation and dechlorination; addition of organic antiscalant; addition of citric acid as an antiscalant; and addition of tannic acid as an antiscalant and antifoulant. Both polyacrylate and tannic acid showed some promise as an alternative to acid pretreatment and chlorination. A new assay was developed which holds promise for predicting the potential of any feed water sample to promote microbial fouling. (Baker-IVI)

DESALINATION OF COALMINE DRAINAGE WATER BY REVERSE OSMOSIS,
Binnie and Partners, London (England).
R. C. Squires, J. A. C. Cowan, and F. C. Wood.
Desalination, Vol. 47, p 343-350, 1983. 5 Fig, 1 Tab.

Descriptors: *Desalination, *Mine drainage, *Reverse osmosis, Ion exchange, Coal mines, Membranes, Wastewater treatment, Wastewater renovation.

A small pilot plant has been built and operated to study the treatment of a mine drainage water of bicarbonate type to render it suitable for use as boiler feed make-up or disposal. To avoid the need for excessive dosing with acid, pre-softening of the feed by ion exchange was adopted and a range of types of reverse osmosis membranes comprising tubular, spiral-wrap and hollow-fine fiber geometries was tested. Best results were obtained with thin-film composite type membranes, salt rejection of over 99% being obtained in a single-pass operation with recyle of concentrate. The preferred process also makes possible the recovery of soda ash from the minewater, after thermal concentration. (Author's Abstract)

3B. Water Yield Improvement

POTENTIAL FOR WATER YIELD AUGMENTATION FROM FOREST MANAGEMENT IN THE EASTERN UNITED STATES,
Southeastern Forest Experiment Station, Asheville, NC. Coweeta Hydrologic Lab.
J. E. Douglas.
Water Resources Bulletin, Vol. 19, No. 3, p 351-358, June, 1983. 6 Fig, 2 Tab, 34 Ref.

Descriptors: *Water yield improvement, *Forest management, Streamflow, Land management, Water demand, Eastern United States.

Generally high rainfall and extensive forests in the East combine to produce excellent potential for managing forests for increased water yield. Models are presented that allow prediction of streamflow increase from hardwood and pine forests on a year-by-year basis. They are being routinely applied in land management planning on National Forests in the Southeast. A recent, independent test indicates that cumulative water yield increases can be predicted within about 14% of the actual value. However, because of the diverse land ownership patterns and the economic objectives of owners, realizing the full potential appears greatest where the land is publicly owned, but demand for water in the East has not reached the point where need for water dictates management prescriptions. POTENTIAL FOR WATER YIELD AUGMENTATION FROM FOREST MANAGEMENT IN THE ROCKY MOUNTAIN REGION,
Rocky Mountain Forest and Range Experiment Station, Fort Collins, CO.
C. A. Troendle.
Water Resources Bulletin, Vol. 19, No. 3, p 359-373, June, 1983. 17 Fig, 4 Tab, 30 Ref.

Descriptors: *Forest management, *Water yield improvement, *Rocky Mountains, Cutting management, Subalpine zone, Lapine zone, Evapotranspiration, Snowpack, Forest hydrograph.

With the exception of the Sierra-Cascade mountain ranges, the Rocky Mountain chain is the only portion of the western United States that consistently yields more than 3 cm of flow annually. Ten to 15% of the land mass in the region produces the majority of the total flow. These source areas are primarily the high-elevation alpine and subalpine forest zones. Because of the dominant effect of the snowpack on the annual hydrograph, management opportunities in the snow zone are an integration of responses from snowpack manipulation as well as evapotranspiration modification. Water yield can be increased significantly through forest man-

agement while minimizing the detrimental effects in terms of peak discharges, erosion and sediment production, and channel integrity. Through prudent management, a 2 to 6 cm increase in flow from each ha of land managed to optimize water yield in the subalpine can be realized. The optimal harvest design appears to consist of small openings, irregularly shaped, and about 3 to 8 tree heights in width parallel to the wind. The amount available for such management is only a small portion of the total. Once under management, given a 100- or 120-year rotation, a maximum increase could be maintained from 1/4 to 1/3 of the managed land at any one time because of the effect of recovery. Augmenting water yield through forest management is a viable alternative in the Rocky Mountain region. (Moore-IVI)
W84-01921

WATER YIELD IMPROVEMENT POTENTIAL BY VEGETATION MANAGEMENT ON WESTERN RANGELANDS,
A. R. Hibbert.
Water Resources Bulletin, Vol. 19, No. 3, p 375-381, June, 1983. 3 Fig, 1 Tab, 42 Ref.

Descriptors: *Range management, *Water yield improvement, *Vegetation management, Brush control, Snow management, Chaparral, Shrubs, Aspen, Pinyon, Juniper, Grassland.

Increasing water for onsite and offsite uses can be a viable objective for management of certain western rangelands. An attractive alternative to water harvesting is to replace vegetation that uses much water with plants that use less so that more water percolates through the soil to streams and ground water. Most sites are too dry to increase water yield in this way; probably less than 1% of the western rangelands can be managed for this purpose. However, where annual precipitation exceeds about 450 mm (18 inches) and deep-rooted shrubs can be replaced by shallow-rooted grasses, there is potential to increase streamflows and to improve forage for livestock. The response to treatment appears to be largest in chaparral and somewhat less in other dense brushlands and in aspen. Small increases are possible by thinning ponderosa pine. Little or no increase can be expected by eradication of low-density brush and pinyon-juniper woodlands. On semidesert shrublands and grasslands, the only opportunity to increase streamflow is to increase the overland flow component. Some potential exists to increase water yield on high-elevation grasslands and sagebrush lands by management of blowing snow. With periodic maintenance to prevent shrub regrowth, the long-term water yield increase from chaparral conversion is expected to average 60 mm per year over areas actually converted. The expected increase for mountain brush is about 50 mm per year if conversion is maintained. Even larger increases are possible by removing aspen trees. (Moore-IVI)
W84-01922

POTENTIAL FOR AUGMENTING WATER YIELD THROUGH FOREST PRACTICES IN WESTERN WASHINGTON AND WESTERN OREGON,
Pacific Northwest Forest and Range Experiment Station, Corvallis, OR. Forestry Sciences Lab.
R. D. Harr.
Water Resources Bulletin, Vol. 19, No. 3, p 383-393, June, 1983. 6 Fig, 6 Tab, 15 Ref.

Descriptors: *Water yield improvement, *Forest management, *Washington, *Oregon, Seasonal distribution, Logging, Water demand, Fog interception, Phreatophytes.

Western Washington and western Oregon comprise a water-rich region that has a very uneven annual distribution of both precipitation and streamflow. Highest demand for water coincides with lowest streamflow levels between July 1 and September 30 when less than 5% of annual water yield occurs. Increases in annual water yield in small, experimental watersheds in the region have ranged up to 600 mm after entire watersheds were logged and up to 300 mm in watersheds that were 25 to 30% logged. Most of the increase has occurred during the fall-winter rainy season, and yield increases have been largest during the wettest years. Estimated sustained increases in water yield from most large watersheds subject to sustained yield forest management are at best only 3-6% of unaugmented flows. Realistically, watersheds in this region will not be managed to produce more water. Water yield augmentation will continue to be only a small and variable by-product of logging. The utility of water yield augmentation is limited by its size and by its occurrence relative to the time of water demand. In some local areas, reduction of fog interception and drip or establishment of riparian phreatophytic hardwoods may reduce summer flows. (Author's abstract)
W84-01923

POTENTIAL FOR INCREASING STREAMFLOW FROM SIERRA NEVADA WATERSHEDS,
Pacific Southwest Forest and Range Experiment Station, Soda Springs, CA. Central Sierra Snow Lab.
R. C. Kattelmann, N. H. Berg, and J. Rector.
Water Resources Bulletin, Vol. 19, No. 3, p 395-402, June, 1983. 3 Fig, 3 Tab, 42 Ref.

Descriptors: *Water yield improvement, *Watershed management, *Forest management, *Sierra Nevada, California, Vegetation management, Snowpack, Evapotranspiration, Snow interception, Streamflow delay.

The Sierra Nevada produces over 50% of California's water. Improvement of water yields from the Sierra Nevada through watershed management has long been suggested as a means of augmenting the state's water supply. Vegetation and snowpack management can increase runoff from small watersheds by reducing losses due to evapotranspiration, snow interception by canopy, and snow evaporation. Small clearcuts or group selection cuts creating openings less than half a hectare, with the narrow dimension from south to north, appear to be ideal for both increasing and delaying water delivery in the red fir-lodgepole pine and mixed-conifer types of the Sierra west slope. Such openings can have up to 40% more snow-water equivalent than does uncut forest. However, the water yield increase drops to 1/2-2% of current yield for an entire management unit, due to the small number of openings that can be cut at one time, physical and management constraints, and multiple use/sustained yield guidelines. As a rough forecast, water production from National Forest land in the Sierra Nevada can probably be increased by about 1% (0.6 cm) under intensive forest watershed management. Given the state of reservoir storage and water use in California, delaying streamflow is perhaps the greatest contribution watershed management can make to meeting future water demands. (Author's abstract)
W84-01924

WATERSHED MANAGEMENT FOR JOINT PRODUCTION OF WATER AND TIMBER: A PROVISIONAL ASSESSMENT,
Resources for the Future, Inc., Washington, DC.
J. V. Krutilla, M. D. Bowes, and P. Sherman.
Water Resources Bulletin, Vol. 19, No. 3, p 403-414, June, 1983. 4 Tab, 26 Ref.

Descriptors: *Forest management, *Watershed management, *Water yield improvement, *Cost analysis, Subalpine Zones, Snow interception, Evapotranspiration, Vegetation management, Wildlife, Logging, Hydroelectric power, Habitats.

Removal of forest canopy to reduce interception, evaporation, and transpiration, and to collect blowing snow, etc., increases water yield from small subalpine watersheds. The value of a program to increase streamflows is dependent upon the use made of such water and on the direct value from the vegetation manipulation. Possible benefits of water augmentation include: timber and fuel wood; habitat for desired wildlife species; hydroelectric generation; and the value of water for agriculture, municipal and industrial users. Associated costs include: the cost of access and vegetation removal; value of replaced habitat for displaced wildlife species; cost of facilities to utili
falling water; cost of water conveyance and dist
bution system; and the cost of conveyance f
delivery. The value of a watershed manageme
program was estimated using water yield data fro
Fool Creek, a 714-acre watershed in the Fra
drainage. It is assumed that a watershed is treat
by harvesting 39% in appropriately shaped patch
and that these areas are then harvested repeated
at regular intervals. The value of water in t
region is so great relative to timber that the redu
tion in water yield over time while waiting for t
timber to mature to merchantable size incurs
opportunity cost which is not compensated by t
value of the timber harvested. (Moore-IVI)

Descriptors: *Water yield improvement, *For
management, *Range management, Watersh
management, Water demand, Water supply, H
droelectric power, Vegetation management.

The demand for more water is increasing throug
out the country. Research on upland watershe
clearly demonstrates that water yield can be i
creased using forest and range management pra
tices. The immediate potential for water yield au
mentation is on carefully selected watersheds th
have the bio-physical potential to produce hi
value water under environmentally acceptab
multiple use management. The first such wat
sheds to be managed in all regions are those th
supply municipal-industrial water directly or co
tribute directly and significantly to hydropow
generation. Management of these types of wat
sheds on any large scale will require changes
approaches to economic analysis and in wat
laws. The opportunity to augment water yield a
large scale program may not be as great as h
been demonstrated on small experimental wat
sheds because of many physical and administrati
constraints. There is little incentive for priva
landowners to manage for the production of
commodity they cannot market. The extent
water yield augmentation using vegetation ma
agement will depend on the need for addition
water as well as the alternative means available
meet this need. (Moore-IVI)

n, Plumbing, Pricing.

nse to water shortages and a court decree,
ver Water Department has undertaken a
of programs to restrict water use during
wing season and to develop a conservation
nong customers without imposing unrea-
lifestyle changes. The Denver potable
euse demonstration project, scheduled for
ion in 1983, is designed to determine
potable water that is comparable in qual-
ity to Denver's existing supply can be continuously and reliably produced from secondary sewage effluent. Other water saving programs are the department's restrictions on water use in the summer months and tap allocations. The conservation program embodies a number of well-known methods of reducing water usage, including: retrofitting plumbing fixtures, plumbing code revisions, leak detection, universal metering, and conservation through rate modification. One of the most easily implemented and least controversial programs is the education and public information program. Approximately 80% of all residential water use in the Denver system goes into yard irrigation, mainly bluegrass lawns, during the summer months. The ET (evapotranspiration) program is aimed at reducing the use of water for lawn watering through the use of ET data by homeowners. (Moore-IVI)

CHOOSING THE OPTIMAL WATER CONSERVATION POLICY,
Policy Sciences Associates, Boulder, CO.
W. B. Lord, J. A. Chase, and L. A. Winterfield.
Journal of the American Water Works Association, Vol. 75, No. 7, p 324-329, July, 1983. 6 Tab, 6 Ref.

Descriptors: *Water conservation, *Policy making, Administrative decisions, Public policy, Colorado, Surveys, Public opinion, Colorado.

A random sample survey was made of 600 residential water users who live in three medium-sized communities along the Front Range of Colorado to study public acceptance, effectiveness and financial feasibility of various outdoor water use conservation programs. The study was specifically concerned with conservation of water used for lawn watering, because this type of use accounts for nearly half of the total residential water use in these communities. Policies that provided information about water conservation actions and their consequences or ones that provided information about the need for practicing conservation were the most acceptable to the consumers. Policies that would be more effective in achieving conservation than sole reliance on information were less widely accepted. Still, policies that rewarded consumers who took actions to conserve water and policies that included restrictions on water use that appeared to be both equitable and not too confining were acceptable to most users. Policies that penalized those who did not conserve or policies that included restrictions perceived to be inequitable, severe, or both were unacceptable to most. Conservation pricing was moderately acceptable and would be one of the more effective policies in achieving water use reductions. A substantial majority of users preferred increasing or inverted block pricing to the more common declining block pricing policy. The best combination of water conservation policies for a municipal water utility depends on the relative weights that decision makers place on the three criteria of acceptability, effectiveness, and financial feasibility. Public information is a logical component for any municipal water conservation program. Beyond that, conservation pricing deserves prime consideration for a utility emphasizing either effectiveness or financial feasibility. A utility emphasizing acceptability faces a difficult choice, because there tends to be an inverse relationship between acceptability and effectiveness. (Baker-IVI)

REDUCING WATER DEMAND AND WASTEWATER FLOW,
Brown and Caldwell, Walnut Creek, CA.
W. O. Maddaus, D. S. Parker, and A. J. Hunt.
Journal of the American Water Works Association, Vol. 75, No. 7, p 330-335, July, 1983. 2 Fig, 2 Tab, 6 Ref.

Descriptors: *Water conservation, *Wastewater management, *Domestic water, Water use, Toilets, Showerheads, Faucets, Infiltration, Nonstructural alternatives, California, Dublin, San Ramon, Pleasanton.

The Dublin, San Ramon, and Pleasanton areas of California are located in an inland valley. Wastewater must be exported from the valley and discharged to San Francisco Bay. Water conservation, resulting in reduced volumes of wastewater flow, is considered far more cost-effective than increasing disposal capacity. Inside residential water use of wastewater flow could be reduced by about 10% if low-flush toilets, low-flow showerheads, and low-flow lavatory faucets were installed throughout the area. Such fixtures are now required for new construction in California. Retrofitting existing homes could be accomplished with an aggressive program to make older homes more water efficient. Infiltration from overwatering of lawns, leaking plumbing, or both accounts for 15 to 30% of measured wastewater flow from homes. (Moore-IVI)

In anticipation of a severe water supply shortfall that could occur within the next 20 years, a limited domestic water conservation program was undertaken in East Brunswick, N.J. The implementation of the first phase of the water master plan is described and analyzed. One important finding is the evidence that the public will cooperate with a water conservation program, even in the absence of strong external incentives such as a drought. Two thirds of the householders in the first phase of the study voluntarily installed at least one of the devices when told of the benefits to the township and of the private monetary benefits to them, along with receiving two letters from municipal officials urging their cooperation. Statistical measures of the resulting water savings were developed from field studies. It was estimated that a program of this nature would save East Brunswick an average of 18964 L of water per home each year. This figure is comparable to the savings measured in two studies in California in 1977. Water may be produced by investing in new wells, reservoirs, pipelines, and pumping and treatment plants, but utilities can also produce new water through water saving techniques. While this is not the ultimate answer to the nation's growing water supply problems, it is nevertheless both effective and cost effective. It is a strategy that should be more seriously and more widely used in the long run management of water resources. (Baker-IVI)

MINIMUM-FLOW PLUMBING FIXTURES,
Wisconsin Univ.-Madison. Dept. of Civil and Environmental Engineering.
R. L. Siegrist.
Journal of the American Water Works Association, Vol. 75, No. 7, p 342-347, July, 1983. 1 Fig, 3 Tab, 38 Ref.

Descriptors: *Water conservation, *Plumbing fixtures, Domestic water, Minimum-flow fixtures, Cost effectiveness.

Minimum-flow plumbing fixtures and household appliances, designed to reduce water consumption by 50 to 90%, provide comparable service, are functionally similar to conventional products, are compatible with utility systems, and are potentially cost-effective. Further development and use of the products are warranted, particularly for domestic uses. Dramatic reductions in water demand resulting from the use of minimum-flow fixtures can have a significant effect on water, wastewater, and energy services. Despite the successful use of minimum-flow plumbing fixtures, there are factors that hinder their development and widespread application. These barriers are a mixture of technical,

social, economic, and institutional factors. (Moore-IVI)

WATER USAGE AND THE QUANTIFICATION OF UNACCOUNTED WATER IN A UNIVERSALLY METER SUPPLY AREA,
J. H. Philips.
Journal of the Institution of Water Engineers and Scientists, Vol. 37, No. 4, p 325-335, August, 1983. 2 Fig, 7 Tab, 6 Ref.

Descriptors: *Leakage, *Water loss, Monitoring, Water usage, Metering, Water distribution.

The only reliable means of ascertaining leakage in a distribution system is to take the summation of the individual minimum hours consumption on a number of waste metered zones and to express this as a minimum consumption for the total area considered; or to set up a section of the distribution network fed by one service reservoir and to measure the drop on that reservoir over a period of time and select the minimum hours consumption, preferably on a holiday or non-working night, and to deduct from this any unknown metered consumption during the minimum hours. If this is done it is possible to take the remaining quantity as the leakage on the system, which should not exceed 2.25 l/house/hr. This is some 12% of the average consumption. Elimination of a quantity lower than this is likely to be uneconomic. The effect of variation of industrial and trade metering policies and municipal and water service uses on the unaccounted for percentage of the water produced at source works is also demonstrated. The need for reliable statistics obtained from accurate field data is a continuing requirement for management of a water undertaking. (Baker-IVI)

WATER RE-USE IN PROCESSING OF PACIFIC SHRIMP,
Castle and Cooke, Inc., San Jose, CA.
L. A. Nielsen, R. J. Price, and P. A. Carroad.
Journal of Food Science, Vol. 48, No. 4, p 1056-1060, July-August, 1983. 10 Fig, 2 Tab, 6 Ref.
NOAA grant NA80AA-D-00120.

Descriptors: *Water conservation, *Water reuse, *Food processing industry, Shrimp, Fluming, Counter current flow, Cost analysis.

A Pacific shrimp (Pandalus jordani) processing plant was instrumented to measure water usage. Water consumption in the conventional processing amounts to 25-40 gallons of potable water to produce 1 lb. of finished shrimp. A water balance was completed which identified fluming as a main user of water and subject to design improvements. Re-use of water in fluming was investigated in pilot plant simulation to evaluate alternatives to fresh flow usage. A counter current flow system was designed to reduce water usage from 264 gpm to 156 gpm with acceptable microbiological quality. An economic analysis of the impact of counter current water re-use was accomplished using the actual plant operating rate of 430 lb. of shrimp per peeler. Calculations were based on processing one million pounds in a six month season. The total annual savings as a result of the recycle modification would be between $1,400 and $4,500, depending on the municipal and sewer rates. (Moore-IVI)

EFFECT OF SYNTHETIC CONDITIONERS ON SOIL WATER RETENTION, HYDRAULIC CONDUCTIVITY, POROSITY AND AGGREGATION,
American Univ., Beirut (Lebanon). Dept. of Soils, Irrigation and Mechanization.
M. N. Nimah, J. Ryan, and M. A. Chaudhry.
Soil Science Society of America Journal, Vol. 47, No. 4, p 742-745, July-August, 1983. 2 Fig, 2 Tab, 17 Ref.

Descriptors: *Soil conditioners, *Soil water, *Sand, *Clays, Soil texture, Arid lands, Permeability coefficient, Soil porosity, Lebanon.

Soils of extremes in texture - either sands or clay, present problems in the use of synthetic soil conditioners in the modification of soil water relationships especially in arid regions. Hygromull (a urea formaldehyde) and Agrosil LR and Agrosil S (amorphous sodium hydrosilicates) were evaluated in the laboratory on soils of different textures. Soil samples were selected from three locations in Lebanon: Leba'a in the south; Furzol in the central Beka'a valley; and Sheia'h near Beirut on the coast. Available water content was increased by Hygromull and Agrosil LR. Saturated hydraulic conductivity of the clay soils was improved by Hygromull, while that of the sandy soil was reduced by Agrosil LR. Hygromull increased porosity of all soils but, unlike Agrosil LR, had no effect on aggregation. Agrosil S had no effect on any property studied. Hygromull has greatest potential for commercial use since it was comparatively effective with both sandy and clay soils. While Agrosil LR is likely to be of some benefit in sandy soils, the acidic S form of this material is ineffective and warrants no further testing. (Moore-IVI)

SOIL WATER CHANGE AS RELATED TO POSITION OF WHEAT STRAW MULCH ON THE SOIL SURFACE,
Agricultural Research Service, Akron, CO. Central Great Plains Research Station.
D. E. Smika.
Soil Science Society of America Journal, Vol. 47, No. 5, p 988-991, September-October, 1983. 3 Fig, 2 Tab, 7 Ref.

Descriptors: *Fallow, *Mulches, *Straw, *Soil water, Evaporation, Water loss, Wind, Great Plains.

A field study was conducted in the Central Great Plains to determine the effects of the position of wheat straw mulch on soil water change of a silt loam soil (a montmorillonitic, mesic Aridic Paleustoll) during three 14-month fallow periods. Treatments of 4600 kg/ha of wheat straw mulch flat on the soil surface, 3/4 flat and 1/4 standing, or 1/2 flat and 1/2 standing (normal position following standard combine harvesting) were compared with bare soil. Standing stubble was 0.46 m tall. Soil water content of one 1 cu m hydraulic lysimeter within each treatment was measured daily and changes summed for each week, and at a distance of 2 m from each side of the lysimeter a neutron depth probe was used to determine soil water content weekly except when the soil was frozen. The relationship of soil water change for each weekly period with weekly values of total precipitation, total open-pan (U.S. Weather Bureau Class A) evaporation, average daylight-hour vapor pressure deficit, average maximum air temperature, average daily air temperature, average daylight-hour air temperature, total solar radiation, and average daily wind movement, was determined by single and multiple-correlation techniques. Soil water increases were related only to precipitation events with the highest correlation resulting from the 1/2 flat 1/2 standing wheat straw position treatment. Soil water losses were best correlated with wind movement with r(2) values of 0.55, 0.41, 0.41, and 0.32 for bare soil, flat 3/4 flat-1/4 standing, and 1/2 flat-1/2 standing treatments, respectively. Soil water loss occurred from both bare soil and where the mulch was flat with winds of 0.08 M/S. When 1/4 or 1/2 of the mulch was standing, a wind of at least 0.55 M/S was needed before soil water loss occurred. Standing wheat straw does not function as a wick for loss of water from the soil. EFFECT OF EXCHANGEABLE SODIUM AN GYPSUM ON SURFACE RUNOFF FRO LOESS SOIL,
Agricultural Research Organization, Bet-Dag (Israel). Inst. of Soils and Water.
R. Keren, I. Shainberg, H. Frenkel, and Y. Kalo.
Soil Science Society of America Journal, Vol. 4 No. 5, p 1001-1004, September-October, 1983. Tab, 17 Ref.

Descriptors: *Surface runoff, *Exchangeab sodium, *Gypsum, Soil conditioners, Soil infiltr tion, Soil surface, Soil crust, Loess.

Surface runoff from a deep silt loam loess soil two exchangeable sodium percentage (ESP) valu (4.6 and 19.3), and the beneficial effect of industri gypsum, were studied in field plots (of 150 sq each) under natural rainfall conditions. The ESP the soil was found to have a very pronounce effect on the surface runoff in spite of the fact th the final infiltration rate of the soil was affecte only slightly by the ESP of the soil. The effect ESP on the percent of surface runoff is probabl through its effect on the rate of crust formatio The percent of surface runoff increase during th rainy season, for both ESP levels, because th runoff from already crusted soil was higher. Hov ever, the effect of consecutive storms depended o the degree of drying between storms. Applicatio of industrial gypsum was found to be very effe tive in lowering surface runoff from the so Spreading the gypsum over the soil was mo effective than mixing it in the upper 10 cm of so by disk. Localization of the gypsum at the so surface, where crust is formed, explains this effec Gypsum application lowered the ESP of the upp 10-cm layer for both gypsum treatments. Since th ESP of the soil in both gypsum treatments wa about the same, it seems that the most importa factor which controlled infiltration was the ele trolyte concentration in the percolating solutio (Author's abstract)

s concern all over the world in industrial-untries as well as in developing countries to e the standards of rural water supplies. A udy was made of about 300 small public in Great Britain to obtain some way of factors into perspective. Of the supplies ed the source in 9 cases was boreholes, 67 of reservoirs, 69 used streams, 38 springs 10 the source of water was undefined. Of supplies, 29 had coagulation with filtration netimes settlement, flows being as small as bic meters/day. In general these were or at least visited daily. A total of 56 ad slow sand filters, mostly of the Scottish type. Some 29 supplies had pH adjust-There were no cases of the use of ozone or e dioxide and only a few places used ultra-radiation for disinfection. Of all sites, 42% had no disinfection at all and the remainder used chlorination. Chlorine gas was used on 23% of the supplies, disinfection with hypochlorite solution was reported for 30%, and calcium hypochlorite tablets were used on 4%. A few of the largest works in the survey were manned on the day shift, but visits were the norm for small supplies. About 31% reported daily visiting, 27% visited two or three times per week and 42% visited weekly. Quality surveillance is the responsibility of scientific services and the frequency of quality sampling varies from weekly to every six months. However, even with the sometimes primitive simplicity with which these supplies are maintained, cases of water-borne diseases are very rare. (Baker-IVI)

CURRENT ISSUES AND FUTURE NEEDS IN URBAN STORM DRAINAGE,
Hydraulics Research Station, Wallingford (England).
P. J. Colyer, and B. C. Yen.
Water Research, Vol. 17, No. 9, p 1067-1071, Sept, 1983.

Descriptors: *Storm drainage, Drainage, Runoff, Rainfall-runoff relationships, Model studies, Urban drainage, Storms.

Discussions and observations made during a conference on urban storm drainage are summarized. Various phenomena have recently occurred which have produced a renewed interest on the international level in urban storm drainage. Several nationally co-ordinated research and application programs have been developed. Knowledge is needed in areas such as the temporal and spatial variations of storm rainfalls, practical and reliable routing techniques for unsteady sewer flow, and the nature of overland flow. The process of storm rainfall, surface flow, pollution entrainment and transport and unsteady flow in sewers lends itself in a particularly satisfying way to mathematical simulation. However, there are trends in both the direction toward sophisticated modelling and towards simplification. Drainage management, with its need for detailed knowledge of the hydraulic performance of existing systems under specified rainfall conditions, will probably demand computer modeling of surcharged networks. However, the computer will not meet all the needs of drainage engineers. The proper collection of data is of extreme importance along with determining what to measure and how to generalize observed results in storm water quality studies. (Baker-IVI)

IMPACT OF DROUGHTS AND FLOODS ON THE ENVIRONMENT,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
M. Khublarian.
Ambio, Vol. 12, No. 2, p 78-79, 1983. 3 Fig.

Descriptors: *Droughts, *Floods, Flood control, Environmental effects, Runoff, Irrigation.

The future may be freed from the environmental, social, and economic devastation brought on by floods and droughts. Advances in research can create means and methods for actively influencing the atmospheric processes that cause these natural disasters. Although the problem of floods and droughts can be radically solved by means of runoff regulation, creating the irrigation systems and application of various irrigation methods requires massive infusions of funds. The development of reliable technological and socio-economic means of prediction and control might eliminate the need for drastic, costly measures now in use. These pro-ecological means will stress optimization of physio-geographic characteristics, river basin protection, and careful treatment of the environment. The long term goals can only be achieved through cooperative efforts and an international sharing of scientific and technological knowledge. (Baker-IVI)

RIVER BASIN MANAGEMENT,
Economic and Social Commission for Asia and the Pacific (UN), Bangkok (Thailand).
V. R. Pantulu.
Ambio, Vol. 12, No. 2, p 109-111, 1983. 3 Fig, 3 Ref.

Descriptors: *River basins, *Water management, International agreements, River management.

Very little information exists that could provide a basis for the formulation of universally applicable principles or arrangements for international river basin management or for sharing of waters. International river basin management ranges from marginal or no cooperation among the co-sharers to a fairly high degree of harmonious cooperation. In cases where no cooperation exists between co-sharers the principal reasons appear to be disparity in economic and technological development between cosharers; mistrust of the political intentions and objectives of neighbors; and lack of genuine international interest in encouraging regional development in the basin due to the political stance of one or more of the co-riparians. Efforts are needed to evolve relatively simple and inexpensive assessment techniques and procedures for gathering basic data; conducting studies on the effects of various types of land uses on water yield, retention and quality, under different typical situations, with the object of deriving information that could be used for planning purposes; training technicians from low-latitude countries in river basin management and regional planning; and conducting comprehensive case studies on river basin management and equitable sharing of resources in ecologically representative major river basins in different parts of the world. SUB-OPTIMAL CONSTANT-VOLUME CONTROL FOR OPEN CHANNEL NETWORKS,
Cagliari Univ. (Italy). Inst. of Electrotechnics.
G. Corriga, S. Sanna, and G. Usai.
Applied Mathematical Modelling, Vol. 7, No. 4, p 262-267, August, 1983. 10 Fig, 3 Ref.

Descriptors: *Automation, *Open channels, *Networks, Mathematical models, Gates, Canals, Simulation.

A state variable mathematical model for use in the synthesis of automatic control systems for open-channel networks is presented. The system considered here consists of n-cascaded reaches joined by control gates. The linear time invariant model consists of a controllable and observable representation where the state variables are the stored water volume variations in each reach and the control signals are the variations of the control gates opening sections. The model derives, through appropriate simplifications, from a more complex one in terms of transfer functions which was derived by linearizing the Saint-Venant equations. The problem of a linear quadratic optimal regulator is formulated in classical terms for the canal system and the constant-volume control laws obtained for the simplified model have been imposed on the complex one: such a control is therefore to be considered sub-optimal. The results of a digital simulation of the controlled system behavior indicate that the system operates with practically constant stored water volumes in each reach and that such behavior is fairly close to that of a pressure-water pipe system. GROUNDWATER LAWS: OPPORTUNITIES FOR MANAGEMENT AND PROTECTION,
Calhoun, Hubbard, Riddle and Cox, Savannah, GA.
W. W. Ballew, III.
Journal of the American Water Works Association, Vol. 75, No. 6, p 280-287, June, 1983. 3 Fig, 24 Ref.

Descriptors: *Water law, *Groundwater management, *Georgia, Federal jurisdiction, State jurisdiction, Legal aspects, Groundwater pollution,

Waste disposal, Water pollution control, Groundwater depletion, Permits, Hazardous materials.

Present and future protection of the nation's groundwaters depends on controlling the interrelated problems of excessive withdrawals and contamination. The existing legal authority and gaps in federal and state regulatory laws as they apply to use of aquifers underlying the state of Georgia were identified. The findings of this prototype case study could be applied in many states to coordinate and enhance groundwater protection, thus assuring the availability and safety of this natural resource. The Ground Water Use Act represents Georgia's primary groundwater protection statute. The act requires major users to obtain a permit before making withdrawals, but uses for agriculture are excluded from permit requirements. Through the Hazardous Waste Management Act and the Hazardous Waste Management Authority Act, Georgia has begun an attempt to supervise the disposal of dangerous wastes. Though Georgia has coordinated its statutes well with federal laws, the need to reach agreements with neighboring states remains. (Moore-IVI)

AQUIFER THERMAL ENERGY STORAGE: AN ATTEMPT TO COUNTER FREE THERMAL CONVECTION,
Auburn Univ., AL. Dept. of Civil Engineering.
F. J. Molz, J. G. Melville, O. Guven, and A. D. Parr.
Water Resources Research, Vol. 19, No. 4, p 922-930, August, 1983. 16 Fig, 3 Tab. 12 Ref. DOE subcontract B-67770-A-0.

Descriptors: *Injection wells, *Thermal energy storage, *Recovery wells, Aquifers, Geohydrology, Transmissivity, Heat conduction, Mobile, Alabama.

In an attempt to counter the detrimental effects of convection on aquifer thermal energy storage (ATES), a dual recovery well system was constructed at a Mobile (Alabama) site and an injection-storage-recovery cycle performed. Using a partially penetrating well, cycle 3-3 injection began on April 7, 1982. A total of 56,680 cu m of 79 C water was injected. After 57 days of storage, production began with a dual recovery well system. Due to the dominating effect of nonhomogeneities, the dual well system did not work particularly well, and a recovery factor of 0.42 was achieved. The degree of aquifer heterogeneity at the location of the present experiments was not apparent during previous experiments at a location only 109 m away, although pumping tests indicated similar values of transmissivity. Therefore aquifers with the same transmissivity can behave quite differently in a thermal sense. Heat conduction to the upper aquitard was a major energy loss mechanism. Water sample analyses indicated that there were no important changes in the chemical constituents during the set of experiments. There was a 19% increase in total dissolved solids. At the end of injection, the land surface near the injection well had risen 1.39 cm with respect to bench marks located 70 m away. The average elevation gradient was 0.0002. Depending on local stratigraphy, injection temperature, and injection volume, elevation changes 2 or 3 times greater than those observed at the Mobile site seem possible. (Moore-IVI)

LEAKY ACRES RECHARGE FACILITY: A TEN-YEAR EVALUATION,
Agricultural Research Service, Fresno, CA. Water Management Research Lab.
H. I. Nightingale, J. E. Ayars, R. L. McCormick, and D. C. Cehrs.
Water Resources Bulletin, Vol. 19, No. 3, p 429-437, June, 1983. 5 Fig, 5 Tab, 15 Ref.

Descriptors: *Groundwater recharge, *Artificial recharge, Costs, Recharge basins, Recharge rate, Turbidity, Alluvial soils, Soil surface, Storm runoff, Soil erosion, Water quality, California, Fresno, Leaky Acres Recharge Facility.

From 1971-1980, studies were conducted at the Leaky Acres Recharge Facility, Fresno, California, to identify and quantify the factors that determine the long term (10-year) effectiveness of basin type artificial ground water recharge through alluvial soils. High quality irrigation water from the Kings River was used for recharge. Construction and land costs for the present expanded facility 83 ha (205.2 ac) using three parcels of land were $1,457,100. The nine-year annual mean costs for only canal water, maintenance, and operation were $110.42/ha.m ($13.62/ac.ft) based on an average recharge rate of 1338 ha.m/yr (10,848 ac.ft/yr) at 86% facility efficiency. The measured end of season recharge rate averaged 14.97 + or - 0.24 cm/day. The 10-year mean actual recharge rate based on actual water delivered, total ponded area, and total days of recharge was 12.1 cm/day. The success of the project is related to: the low turbidity, nutrients, and salt content of the input water; permeable sandy surface soils and favorable subsurface geology that allows rapid horizontal movement of the water; good management to control the major biological factors leading to clogging of the surface soils; and cooperation between the irrigation district that delivers the water, city personnel who manage the facility, and research personnel. The major problems are related to soil erosion within the basins, and the resulting surface sealing with fine soil particles, as governed by the ground surface slopes in the borrow strip for soils used to built the levees. The continued success of this recharge project is highly dependent upon keeping turbid storm runoff water out of the basins. (Moore-IVI)

Descriptors: *Agricultural runoff, *Grazing, *Cattle, *Soil loss, Vegetation, Environmental effects, Pasture management, Precipitation, Ohio.

Five small watersheds (0.25-3.1 ha) on sloping uplands in eastern Ohio were used to evaluate environmental effects of a beef management program of rotational summer grazing on one area, and rotational winter grazing/feeding with stored hay on another area. During the 5-y study, annual precipitation was 1080 mm, which was 8-15% greater than the long-term average. The surface runoff was measured by precalibrated H-flumes, and automatically sampled using Coshocton wheels. Surface runoff from watersheds with beef cattle management increased, compared with the long-term averages when hay was grown on the watersheds. Greater precipitation was the primary factor causing more runoff during the growing season (May-October), and the cattle management was a major contributing influence on the runoff increase during the dormant season (November-April). Maintenance of good vegetative cover on the study areas was a major factor in limiting annual average surface runoff to < 110 mm, which was a relatively small amount. The large runoff events, although a small percentage of the total number of events, produced most of the runoff volume. Soil loss from these pastures was minima

LONG-CHAIN ALKYBENZENES AS MOLECU LAR TRACERS OF DOMESTIC WASTES I THE MARINE ENVIRONMENT,
Massachusetts Univ., Boston.
R. P. Eganhouse, D. L. Blumfield, and I. R. Kaplan.
Environmental Science and Technology, Vol. 17 No. 9, p 523-530, September, 1983. 6 Fig, 3 Tab, 4 Ref. DOE contract EY-76-3-03-0034.

Descriptors: *Environmental tracers, *Domesti wastes, *Municipal wastes, Linear alkylbenzenes Surfactants, Marine environment, Marine sedi ments, Particulates, Alkyl benzenes, Los Angeles California.

A suite of secondary C10-14 substituted benzene known as linear alkylbenzenes (LABs) were found in southern California's municipal wastes. These compounds are manufactured for the production o the linear alkylbenzenesulfonate (LAS) surfactant used in commercial detergent formulations. Thus their appearance in wastes is believed to result from incomplete sulfonation of the linear alkylben zenes and subsequent carryover in detergents and/ or by desulfonation of LAS. LABs were evaluated as waste tracers in the marine environment by determining their concentration and composition in suspended particulate matter and sediments in the vicinity of a major wastewater outfall system. They appear to be preserved in sediments for time periods of 10-20 years. A complex assemblage o surfactant-related branched alkylbenzenes was also found in the waste-affected sediments. Sedimentary distributions of both the linear and branched alkyl benzenes are discussed in terms of the historical emission of wastes in Los Angeles and surfactant usage rates. The results demonstrate that LABs are potentially useful as molecular tracers of domestic wastes and, under appropriate conditions, as geochronological tools. (Author's abstract)

ccurrence of chlorinated organic material in iquors from the bleaching of kraft pulp is an ble result of the common practice of using a bleaching agent. Although more than 100 ated organic compounds have been identi- untreated process effluents from the kraft ing process, far fewer chlorinated organics een found in biologically treated combined ed kraft mill effluent. Biologically treated ed mill effluents sampled at nine softwood ed kraft mills located across Canada were ed for chlorinated neutral organic com- . The test results showed only four main ated compounds: chloroform (7-105 micro dichlorodimethyl sulfone (64-429 micro g/ chlorodimethyl sulfone (0.3-12.4 micro g/L), ntatively) tetrachlorodimethyl sulfone (0.4- ro g/L). Unlike chloroform, the chlorinated s were found to be relatively resistant to l by biological treatment in an aerated . However, preliminary assessment of fish mulation potential, acute fish toxicity, and mutagenicity indicated that the chlorinated s would have no immediate adverse effect aquatic environment. ptors: *Population dynamics, *Rotifers, say, Water quality, Monitoring, Toxicity, onus.

opulation dynamics of the monogonont ro- rachionus rubens were used under con- trolled experimental conditions as a sensitive bioassay for toxic substances in sublethal doses. Even slight reductions in organism fertility and life expectancy were reflected at the integrated level of population dynamics. Serving as bioindicators for the standard test are the population parameters intrinsic rate of natural increase (r), carrying capacity (k), frequency (f), and pregnancy of the density oscillations (p). The optimal spreading power (steepest slope of the response curves) lies at different concentration areas for each parameter, so that they can be used specifically in standard tests. TOTAL ALKALINITY VERSUS BUFFER VALUE (CAPACITY) AS A SENSITIVITY INDICATOR FOR FRESH WATERS RECEIVING ACID RAIN,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Environmental Science.
S. D. Faust.
Journal of Environmental Science and Health, Vol. A18, No. 5, p 701-711, September, 1983. 2 Fig, 4 Tab, 17 Ref.

Descriptors: *Alkalinity, *Acid Rain, *Water quality, Water pollution effects, Indicators, Acidity.

The frequently stated idea that total alkalinity is a measure of the buffer capacity of a natural water is refuted. Total alkalinity is a measure of the acid neutralizing capacity, equivalents/liter, of a water. In natural waters, the carbonate system provides most of this neutralizing capacity. In as much as the pH values of natural fresh waters lie below 8.3, the total alkalinity is, for all intents and purposes, the total bicarbonate content. Any contributions of carbonate and hydroxide to total alkalinity are nil. The buffer capacity or buffer value is the relation between the increment of a strong base, or strong acid, that causes a one unit change in the pH value. The values of total alkalinity and pH, considered individually cannot give an accurate assessment of the impact of acid deposition on a natural water. Rather it is necessary to combine the pH and alkalinity values into the beta concept in order to assess accurately and to calculate the capacity of a natural water to resist the impact of acid deposition. An analytical determination of total alkalinity is given with an application of the beta value. (Baker-IVI)

SIMPLE DETERMINATION OF OXIME CARBAMATES IN SOIL AND ENVIRONMENTAL WATER BY HIGH PRESSURE LIQUID CHROMATOGRAPHY,
Institute for Pesticide Research, Wageningin (Netherlands).
A. Dekker, and N. W. H. Houx.
Journal of Environmental Science and Health, Vol. B18, No. 3, p 379-392, June, 1983. 2 Fig, 2 Tab, 9 Ref.

Descriptors: *Pollutant identification, *Water analysis, *Soil analysis, Aldicarb, Oxamyl, Methomyl, High pressure liquid chromatography, Chromatography.

A method is described for determining residues of aldicarb, aldicarb sulfoxide, aldoxycarb, oxamyl and methomyl in soil, groundwater and surface water. Subsoils were extracted with water and topsoils were extracted with acetone. The aqueous samples were either directly injected after acidification or concentrated by extraction with chloroform. The organic extracts were evaporated to dryness and redissolved in acidified mobile phase. The compounds were detected with a variable wavelength U.V. detector or with a fluorometric detector after a post-column reaction. Compounds within a concentration range from 0.5 ng/ml to 200 ng/ml could be determined with a maximum coefficient of variation of 7.5%. Recoveries varied from 77.0 to 98.8%. (Baker-IVI)

UTILITY OF ENDOTOXINS AS A SURROGATE INDICATOR IN POTABLE WATER MICROBIOLOGY,
Illinois Inst. of Tech., Chicago. Dept. of Environmental Engineering.
C. N. Haas, M. A. Meyer, M. S. Paller, and M. A. Zapkin.
Water Research, Vol. 17, No. 7, p 803-807, July, 1983. 3 Tab, 12 Ref.

Descriptors: *Water quality, *Indicators, *Endotoxins, Coliforms, Bacteria, Potable water, Spectrophotometry.

Whether the measurement of gram-negative bacterial endotoxins could serve as a useful surrogate to the measurement of either total coliforms or standard plate count organisms to determine raw water quality was investigated. The LAL spectrophotometric assay of gram-negative bacterial endotoxin was used for the study. While statistically significant associations were noted between standard plate count, membrane standard plate count and total coliform organisms and total endotoxins, these were at a relatively low coefficient of determination. In the two water treatment and distribution systems studied, endotoxins were observed at levels between 3-14 micrograms/liter. There was little advantage found in the use of the free or bound (total-free) endotoxin analysis in correlating standard bacteriological parameters, and there may be some interference of an unknown nature between the LAL spectrophotometric endotoxic analysis and particulate material present in natural surface, partially treated, and finished potable water. From a practical point of view these findings do not justify the use of the LAL spectrophotometric procedure as a surrogate or rapid measurement of these classical parameters. (Baker-IVI)

COMPARATIVE STUDY ON ORGANIC CONSTITUENTS IN POLLUTED AND UNPOLLUTED INLAND AQUATIC ENVIRONMENTS - V; ORGANIC CARBONS AND HYDROCARBONS IN SEDIMENTS,
Tokyo Metropolitan Univ. (Japan). Dept. of Chemistry.
G. Matsumoto.
Water Research, Vol. 17, No. 7, p 823-830, 1983. 2 Fig, 3 Tab, 23 Ref.

Descriptors: *Organic carbon, *Hydrocarbons, *Sediments, *Pollutant identification, *Sludge, *Wastewater, Japan, Tokyo, Tama River, Ogasawara Islands, Water pollution sources, Urban areas, Industrial wastes, Alkanes, Squalene.

Organic carbons and hydrocarbons were analysed for polluted sediments from Tama River and sludges from night soil and sewage treatment plants in the Tokyo area (Japan) and unpolluted sediments from river and reservoirs from Chichijima Island in the Ogasawara (Bonin) Islands to characterize their features for polluted and unpolluted aquatic environments. In addition the relationships of the features of organic consituents between waters and sediments were given. The contents of n-alkanes (C14-C36), squalane and unresolved complex mixture of hydrocarbons (UCMH) for the sediments from Tama River ranged from 16 to 94, 0.86-15 and 250-1100 micro g/g dry base, which are much higher than those of the sediments from Chichi-jima Island. The major constituents of hydrocarbons in the sediments and sludges from the Tokyo area were mainly odd-carbon numbered n-alkanes and squalene, whereas those of the island were only odd-carbon numbered n-alkanes. Hydrocarbons as carbon (total content x 0.851, as C20H42, HCC)/total organic carbon (TOC), HCC/extractable organic carbon with ethyl acetate (EOC), squalene as carbon (SqC)/TOC, SqC/EOC and UCMH/n-alkane (C15-C33) values for the sediments from Tama River were much higher than those of the sediments from the island, while carbon preference index (CPIH) values for the sediments of Tama River were considerably lower than those of the island. It was thus indicated that HCC/TOC, HCC/EOC, UCMH/n-alkane and CPIH values should be the important indicators of hydrocarbon pollution for aquatic environments. In addition SqC/TOC and SqC/EOC ratios are apparently useful measures of urban-industrial activities on

LIBRARY U. OF I. URBANA-CHAMPAIGN

aquatic environments. The similarity of the nature of hydrocarbons of sediments and sludges from the Tokyo area indicated that the sewage contributed considerably to urban river sediments. Further it was also indicated that hydrocarbons were concentrated in sedimentary environments, although the features of hydrocarbons in sediments are generally similar to those of waters. POLLUTION LEVELS IN SOME NIGERIAN RIVERS,
Ibadan Univ. (Nigeria). Dept. of Preventive and Social Medicine.
P. A. Oluwande, M. K. C. Sridhar, A. O. Bammeke, and A. O. Okubadejo.
Water Research, Vol. 17, No. 9, p 957-963, 1983. 2 Fig, 6 Tab, 22 Ref.

Descriptors: *Pollution load, *Tropical regions, *Rivers, *Nigeria, Water temperature, Wastewater, Water pollution sources, Seasonal variation, Eutrophication, Oxygen, Supersaturation, Light, Bacteria, Water quality.

Surveys of five rivers in a hot-humid zone of a tropical country (Nigeria) were carried out over 3 years by obtaining samples for physical, chemical and bacteriological analyses. The main characteristics monitored were temperature, turbidity, total, dissolved and suspended solids, pH, dissolved oxygen, BOD, ammonia-nitrogen and the coliform counts. In addition, the main characteristics of the liquid waste being discharged into the rivers were determined. During the dry season, the highest mean temperature is 29 C with a range of 5 C and the lowest is 26 C with a range of 3 C. In the wet season, the highest mean temperature is 27.3 C with a range of 2 C while the lowest is 24.5 C with a range of 1 C. The other characteristics vary more widely with seasons. The high temperature in these rivers all the year round encourages pollution by human activities. During the dry season, pollution causes prolific algae boom, which causes oxygen supersaturation during periods of high temperature and abundant sunlight. The physical, chemical and biological characteristics of the rivers deteriorate sharply as they flow through towns annd other human communities. (Author's abstract)

IN SITU PERISTENCE OF INDICATOR BACTERIA IN STREAMS POLLUTED WITH ACID MINE DRAINAGE,
West Virginia Univ., Morgantown. Div. of Plant and Soil Sciences.
N. E. Carlson-Gunnoe, C. B. Law, and G. K. Bissonnette.
Water Research, Vol. 17, No. 9, p 1119-1124, September, 1983. 3 Fig, 3 Tab, 20 Ref.

Descriptors: *Indicators, *Bacteria, *Acid mine drainage, Monitoring, Streams, Fecal coliforms, Coliforms, Streptococci, Domestic wastes.

Persistence of indicator organisms associated with natural samples of raw sewage was studied following in situ exposure to five aquatic environments. Three of these streams contained significant amounts of acid mine water while the other two were relatively uncontaminated. Indicator organisms were rapidly killed upon exposure to the acid mine systems, whereas little reduction in numbers was noted in the uncontaminated streams. Seasonal changes affected survival of indicators as reflected by prolonged persistence at colder in situ water temperatures. The fecal coliform group was most susceptible to the acid mine water stress, while the fecal streptococci were most persistent. An enrichment technique resulted in substantially enhanced recovery of certain species of sublethally injured survivors of acid stress. Enrichment was particularly beneficial for recovery of acid mine water injured fecal coliforms. Relatively little improvement in recovery of fecal streptococci was afforded by the enrichment technique. These findings suggest that dependence on coliform analyses may not be adequate for reliable determination of bacteriological water quality in acid streams. If coliforms are to be used for reliable determination of bacteriological water quality in acid streams, it would seem essential that enrichment techniques be used in order to recover sublethally injured survivors. STABILIZED TEMPERATURE PLATFORM FURNACE WITH ZEEMAN EFFECT BACKGROUND CORRECTION FOR TRACE ANALYSIS IN WASTEWATER,
Bodenseewerk Perkin-Elmer and Co., Uberlingen (Germany, F.R.).
U. Vollkopf, A. Grobenski, and B. Welz.
Atomic Spectroscopy, Vol. 4, No. 5, p 165-170, September-October, 1983. 14 Fig, 1 Tab, 7 Ref.

Descriptors: *Trace metals, *Pollutant identification, *Wastewater analysis, Cadmium, Lead, Chromium, Zeeman effect, Stabilized temperature platform furnace.

Conventional graphite furnace atomic absorption (AA) is often plagued by nonspectral as well as spectral interferences. This is particularly true in the determination of trace metals in complex matrices like wastewater. For the elimination of nonspectral interferences, the Stabilized Temperature Platform Furnace (STPF) concept was applied. To avoid spectral interferences caused by high and structured background, the Zeeman/5000 system was used. The results of the determination of Cd, Cr, and Pb in various wastewaters demonstrate that the application of the STPF concept provides an optimum environment for atomization in a graphite furnace. All of the STPF parameters must be applied to guarantee that the majority of determinations can be carried out free from vapor-phase interferences directly against reference solutions. Matrix modification and peak area integration are important integral parts of the complete concept. The combination of the STPF with Zeeman effect background correction permits in addition the direct determination of ultratrace amounts of metals even in complex matrices where extremely high or structured background plagues conventional graphite furnace AA. Descriptors: *Wastewater analysis, *Drugs, Chromatography, High-pressure liquid chromatography, Gas chromatography, Research facilities.

Tripelennamine hydrochloride, thenyldiamine hydrochloride, and chlorothen citrate have been used as antihistamines and for the treatment of asthma and bronchitis. Toxicological evaluation of these drugs was scheduled as part of a structure-activity relationship study of antihistamines in rats and mice, because of the paucity of such information. Prerequisite for the evaluation was the development of analytical chemical procedures to the concentration, homogeneity, and stab the drugs in dosed feed, to monitor the laboratory personnel to signal their possibl sure to the drugs, and to monitor the was to ensure that the test agents were not dis into the environment. A high-pressure liqui matographic procedure with fluorescence tion was developed for determination of th antihistamines in admixture in animal feed, urine, and wastewater at levels of 500, 10 ng/g, respectively. Data on the partition and use of a silica gel column to aid in the c of sample extracts from the three substra reported for the three test agents. Extracti ciencies and data concerning the stability o lennamine hydrochloride and thenyldiami drochloride in animal feed are presented. D tion of a new route for synthesis of chlo citrate and ancillary data concerning the ga matographic analysis for the three drugs in ture in animal feed at levels as low as 10 mic are also reported. iptors: *Ion chromatography, *Chlorides, tes, *Sulfates, *Sulfur, Water analysis, Rain, water analysis, Interstitial water.

-column ion chromatography using conduc- detection as well as an indirect ultraviolet que was applied to the determination of Cl(- 3(-) and SO4(2-) in samples of rain, sewer , and soil-pore water. Also described are two methods which allow ion chromatographic analysis of CaSO4-extractable nitrate in soils, and total sulfur in soils, marine sediments and plant tissue. Single-column ion chromatography is well suited to rapid, simultaneous analysis for anions in aqueous environmental samples. The relative simplicity and ease of operation are conducive to routine analysis, particularly with the availability of modern data-handling systems which can be directly interfaced with the detector. No interruption of operation is necessary to regenerate a suppressor column, and indirect ultraviolet detection provides lower detection limits than previously possible with conductivity measurements. Pretreatment with a lead-charged cation-exchange resin permits the analysis of samples high in SO4(2-). (Moore-IVI)

DETERMINATION OF CHROMIUM(VI) IN NATURAL WATERS BY THE SORPTION OF CHROMIUM-DIPHENYLCARBAZONE WITH XAD-2 RESIN,
Kyushu Univ., Fukuoka (Japan). Radioisotope Center.
S. Osaki, T. Osaki, and Y. Takashima.
Talanta, Vol. 30, No. 9, p 683-686, 1983. 3 Fig, 2 Tab, 9 Ref.

Descriptors: *Chromium, *Sorption, Water analysis, Organic matter, Natural waters, Seawater, Interference.

The sorption of the chromium(III)-diphenylcarbazone complex (Cr-DPC) with XAD-2 has been investigated, for use in the separation of Cr(VI) from Cr(III) species in natural waters. Cr-DPC is formed from the reaction of Cr(VI) with diphenylcarbazide, but Cr(III) species give no reaction in aqueous solution. The addition of sodium chloride or sodium beta-naphthalenesulfonate markedly enhances the sorption. The Cr-DPC sorbed on XAD-2 can be almost completely eluted with organic solvents, especially methanol, but about 5% of it is irreversibly sorbed and cannot be eluted. The excess of diphenylcarbazide and some of the organic matter in natural waters are also sorbed on XAD-2 but most of the this can also be eluted with methanol. Organic matter which interferes with measurement of the absorbance of Cr-DPC can almost all be removed by extraction and chloroform. By use of these techniques, Cr(VI) in seawater has been determined by the standard-addition method. Although about 50 l of sea-water are necessary for the analysis, organic and colloidal Cr(III) species do not interfere. (Author's abstract)

METHOD FOR RECOVERY OF ENTERIC VIRUSES FROM ESTUARINE SEDIMENTS WITH CHAOTROPIC AGENTS,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
D. A. Wait, and M. D. Sobsey.
Applied and Environmental Microbiology, Vol. 46, No. 2, p 379-385, August, 1983. 1 Fig, 6 Tab, 26 Ref. PHS grant AI17277, DOC grant NA79AA-D-00048.

Descriptors: *Chaotropes, *Enteric viruses, *Estuarine sediments, Poliovirus, Echovirus, Rotairus, Estuaries, Virus recovery.

An evaluation was made of the ability of chaotropes, low-molecular-weight ionic compounds which enhance the solubilization of hydrophobic compounds in water, to improve the recovery of enteric viruses from highly organic estuarine sediments. Chaotropic agents alone were poor eluents of polioviruses from sediment but were effective when combined with 3% beef extract. Chaotropes of lower potency, NaNO3, NaCl, and KCl, were more efficient eluents than the stronger chaotropes, guanidium hydrochloride or sodium trichloroacetate. The most effective eluent was 2 M NaNO3 in 3% beef extract at pH 5.5, which eluted 71% of sediment-associated polioviruses. Efficient concentration of the sodium nitrate-beef extract eluate by organic flocculation required the addition of the antichaotrope (NH4)2SO4 to a 2 M concentration and Cat-Floc T (Calgon, Pittsburgh, Pa.) a cationic polyelectrolyte, to a 0.01% concentration. Dialysis of the final concentrate was necessary to reduce salts to nontoxic levels before assay in cell cultures. Trials with highly organic estuarine sediment seeded with high or low numbers of poliovirus 1, echovirus 1, or rotarvirus SA-11 demonstrated the superiority of this method over two other methods currently in use. (Author's abstract)

Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 2, p 66-71, 1983. 6 Fig, 4 Tab, 24 Ref.

Descriptors: *Bromide, *Iodide, *Gas chromatography, Trihalomethanes, Drinking water, Chlorination, Water treatment, Water analysis.

During oxidative treatment of drinking water (for example with chlorine), trihalomethanes are formed by the reaction between organic matter and the halogens present in water. This formation depends on the concentration of the halogens, which usually are present in microgram quantities. In order to gain an exact knowledge of the mechanism of this formation and the possibility of eliminating the haloforms it is necessary to qualitatively evaluate bromide and iodide in the microgram-range. A gas chromatographic method was developed which allows detection of 50 micro g/l bromide and 5 micro g/l iodide without concentration and 0.5 micro g/l bromide and 0.2 micro g/l iodide with sample concentration. The relatively simple procedure is based on the transformation of the halogens into 2-bromo- or 2-iodohydrine. These derivatives are extracted with ethylacetate and are determined with an electron capture detector. The different retention times between 2-bromo- and 2-iodohydrine make possible the determination of both of the halogens in one sample of water. This method is not subject to interference, which has been proven with water samples of different origin and composition. The method is recommended to be generally used for the determination of bromide and iodide in drinking water. (Moore-IVI)

Descriptors: *Pollutants, *Chemical oxygen demand, *Waste water analysis, Analytical methods, Permanganate, Dichromate, Oxidation.

About 580 mostly organic compounds from all the important classes of substances, of synthetic and natural origin, were tested for chemical oxidizability. The method using permanganate (in acid solution) and dichromate/H2SO4 (without and with Ag+ as a catalyst) were applied in accordance with standard procedures and legislative prescriptions respectively, and the results thereof were compared with published values. The dichromate with Ag+ COD method reached oxidizabilities of nearly 100% of theory with most organic substances, and proved sufficient and adequate for the ingredients of most industrial effluents. In contrast, the permanganate-COD method mostly reaches only up to 10%, often equals 0% of the theory, and is therefore of no relevance. Comparing the 3

different oxidation methods used, the tested compounds may be classified into 4 categories of oxidation efficiency. The values of oxidizability are discussed in respect to the structural groups of the tested compounds. (Author's abstract)

SUBMERGED WATER PLANTS AS TESTING ORGANISMS FOR POLLUTANTS (SUBMERSE WASSERPFLANZEN ALS TESTORGANISMEN FUR BELASTUNGSSTOFFE),
TUV Stuttgart e.V., Filderstadt (Germany, F.R.).Warnetechnik und Umweltschutz.
W. Nobel, T. Mayer, and A. Kohler.
Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 3, p 87-90, 1983. 5 Tab, 13 Ref.

Descriptors: *Aquatic plants, *Bioindicators, *Toxicity, Water pollution effects, Ammonia, Chloride, Phosphates, Boron, Marlon A, Phenols, Heavy metals.

Results of pollution experiments with submerged vascular plants under controlled conditions in the laboratory are presented as results of toxicity tests. It is possible to use submerged macrophytes as biological indicators, especially as testing organisms for water-pollutants. The following substances show toxic effects to submerged macrophytes (first significant damage) in concentrations, which are relevant to the environment: ammonium (5 mg/l NH4), boron (1 mg/l B), chloride (50 mg/l Cl), phosphate (1 mg/l PO4), and Marlon A (0.5 mg/l MBAS). At less realistic concentrations for use as environmental indicators, first significant damages are found for different phenols (cresol 0.22 mg/l, xylenol 0.24 mg/l, phenol 0.56 mg/l), whereas first significant damages for complexed heavy metals occur at concentrations of partial use (copper 0.032 mg/l Cu, zinc 0.65 mg/l Zn, cadmium 0.011 mg/l Cd, lead about 2 mg/l Pb). Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 4, p 132-135, 1983. 3 fig, 3 Tab, 12 Ref.

Descriptors: *Polycyclic aromatic hydrocarbons, *Thin layer chromatography, Water analysis, Drinking water, Hydrocarbons, Wastewater analysis.

According to German drinking water regulations the quantitative analysis for 6 polycyclic aromatic hydrocarbons is necessary. The polycyclic aromatic hydrocarbon include benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, benzo(k)fluoranthene, fluoranthene, and benzo(g,h,i)perlene. The method consists of the separation of these substances by means of one-dimensional thin layer chromatography and fluorescence-spectroscopic quantitative evaluation using a computing integrator (SP 4100 Spectra-Physics). Samples of drinking water, surface water and waste water can be analyzed by this method. A clean-up of the extracts can be necessary before analyzing. (Moore-IVI)

REDUCTION OR SUBSTITUTION OF SILVER SULFATE USING THE STANDARD METHOD FOR CHEMICAL OXYGEN DEMAND (VERMINDERUNG ODER SUBSTITUTION VON SILBERSULFAT BEI DER CSB-STANDARD-METHODE),
Goettingen Univ. (Germany, F.R.). Inst. fuer Agrikulturchemie.
M. G. Eissa.
Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 4, p 136-138, 1983. 3 Tab, 6 Ref.

Descriptors: *Chemical oxygen demand, *Silver sulfate, Water analysis, Wastewater analysis, Nickel sulfate, Copper oxide, Oxalic acid.

The usual standard method (DEV) for chemical oxygen demand (COD) to determine the organic constituent of water and wastewater requires 10g of silver sulfate (Ag2SO4) to be used as an oxidation catalyst. Due to the relatively high dose and the high cost of silver, tests were made to find a way to cut down on the use of silver sulfate or replacing it altogether with either nickel sulfate (NiSO4) or copper oxide (CuO). The effects of comparative methods were tested on water specimens of various origin and on oxalic acid as a monitoring substance. The application of silver sulfate could be reduced to a tenth of the usual quantity without affecting the analytical results (average deviation = 0.6%). The two substitute catalysts, Ni-sulfate and copper oxide, produced, in comparison to Ag-sulfate, similar results when the organic constituent was above 100 mg/l O2 (average deviation = 1.60%). If the COD rate was below this level, the error percentage rose, and showed a negative correlation. It is possible to make use of these oxidation catalysts in areas where the COD is less than 100 mg/l O2, as long as the results can be adjusted by correlation. (Author's abstract)

SIMPLE METHOD FOR DETERMINING THE CATALASE ACTIVITY IN SLUDGE, SEDIMENT, AND WATER (EIN EINFACHES VERFAHREN ZUR BESTIMMUNG DER KATALASE-AKTIVITAT IN SCHLAMMM, SEDIMENT UND WASSER),
Stadtwerke Mainz A.G. (Germany, F.R.).
U. Obst, and H. K. Frank.
Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 4, p 138-139, 1983. 7 Ref.

Descriptors: *Catalase activity, *Electrochemistry, *Microorganisms, Sludge, Sediments, Water analysis, Aerobic metabolism, Hydrogen peroxide.

A simple electrochemical method is presented for determining the catalase activity of the microbial aerobic metabolism in sludge, sediment, and water. After adding hydrogen peroxide to the sample (final concentration of 0.5%) the catalytically produced oxygen is measured by an electrochemical process (Karlsruher Flasche). One to 5 minutes of reaction time permit an exact measurement. Non-biogenic decomposition of hydrogen peroxide is recorded by an inactivated sample. In examining various specimens of sludge, sediment, and water the method was reproducible and simple. Therefore an application is proposed for these purposes. (Author's abstract)

Descriptors: *Pesticides, *Adsorption, *Tenax, *Chromatography, Gas chromatography, Thin layer chromatography, Halogenated pesticides, Carbamate pesticides, Organophosphorus pesticides, Aldrin, Water analysis.

The adsorption properties of Tenax have been studied in order to test the possibility of concentration and recovery of pollutant substances. Pesticides of various classes (chlorinated, phosphorated, carbamates, carbonates) and other organic toxicants having different volatility were employed as substances to be concentrated. They were present in water at 0.1 ppb level of concentration. Recovery was made by solvent extraction or by thermoe lution. Revelation and quantitative analysis wer performed by gas chromatography and b HPTLC. The effect of the flux was investigated Tenax is the most suitable material in comparison with other tested adsorbents. Recovery is general ly good except for aldrin. An apparatus for strip ping and thermoelution is described that allow one to analyze water and air pollutants. Procedure have been tested for single classes of substances o a mixture of them. Descriptors: *Groundwater pollution, *Infiltration, *Groundwater recharge, Organic compounds, Path of pollutants, Chlorinated hydrocarbons, Switzerland.

Two field sites in Switzerland were used to study the behavior of organic micropollutants during infiltration of river water to groundwater. Persistent organic chemicals exhibiting octanol/water partition coefficients smaller than about 5000 moved rapidly with the infiltrating river water to the groundwater, a finding in agreement with predictions from model calculations. The biological processes which were responsible for the elimination of various micropollutants such as alkylated and chlorinated benzenes, occurred predominantly within the first few meters of infiltration. Alkylated benzenes were eliminated at faster rates than 1,4-dichlorobenzene. Anaerobic conditions in the aquifer near the river hindered the biological transformation of 1,4-dichlorobenzene. Among the compounds found to be persistent under any conditions were chloroform, 1,1,1-trichloroethane, trichloroethylene, and tetrachloroethylene. With respect to such chemicals, bank infiltration is ineffective as a first step in the treatment of river water for water supplies. Long-term field measurements are useful to gain relevant insights into the behavior of organic micropollutants in a natural river water-groundwater infiltration system and to check the general validity of conclusions drawn from laboratory investigations. ACID RAIN: A RAPIDLY SHIFTING SCENE,
B. Hileman.
Environmental Science and Technology, Vol. 17, No. 9, p 401A-405A, 1983.

Descriptors: *Acid rain, *Policy making, Administrative decisions, Political aspects, Legislation, Water pollution sources.

Some changes are noted in the concern shown by top levels of the United States government regarding the problem of acid rain. A recent government report indicates that the problem is serious enough to warrant a search for immediate solutions, that emissions of sulfur dioxide and nitrogen oxides are at least 10 times greater from human activities than arises from natural happenings, that the areas receiving the highest deposition are within and downwind of the major source regions, and that some lakes in the major receptor areas have become more acidic in the past two decades. A National Research Council report agrees that the

LIBRARY U. OF L. URBANA-CHAMPAIGN

nt increase of acidic substances in the envi-
ent cannot be arising from natural causes. The
t concluded that there is no evidence for a
g nonlinearity in the relationship between

on coefficients are commonly used to quanti- distribution of organic pollutants between queous and particulate phases of natural c systems. The magnitude of the partition cient for a specific pollutant in a particular has been shown to be related to the octa-ater partition coefficient of the pollutant and ganic carbon content of the solid phase onto sorption occurs. A third variable is impor-the concentration of the sorbing solid phase system. Laboratory partitioning experiments performed over a range of solids concentra-by using three different Lake Michigan sedi-samples as sorbents and four hydrophobic y pollutants (chlorobenzene, naphthalene, richlorobiphenyl, and 2,4,5,2',4',5'-hexach-phenyl) as sorbates. There is a significant se in partitioning as solids concentration de-s. Partition coefficients developed at one ntration of solids are not necessarily appro-at other solids concentrations, and partition cients produced in studies using different ques are not necessarily comparable. The effect is likely to occur in the environment gh the extent of the effect relative to that ed in the laboratory is unknown. (Moore-

TEMPORAL VARIATIONS IN ACID PRECIPITATION OVER NEW YORK STATE-WHAT THE 1965-1979 USGS DATA REVEAL,
Consolidation Coal Co., Pittsburgh, PA.
R. A. Bilonick, and D. G. Nichols.
Atmospheric Environment, Vol. 17, No. 6, p 1063-1072, 1983. 4 Fig, 3 Tab, 10 Ref.

Descriptors: *Acid rain, *Precipitation, *Statistical analysis, Temporal distribution, Hydrogen ion concentration, Sulfates, Nitrates, Calcium, Conductivity, Ion balance.

During the period from 1965 to 1979, the USGS collected rainfall samples throughout New York State. pH, sulfate, nitrate and calcium levels were measured, among other species. The statistical nature of the variation of these quantities with time was examined in this study. A preliminary step involved using ion balances and electrical conductivities to remove inconsistent measurements, which successfully reduced the amount of noise in the data. The time series analysis method of Box and Jenkins was applied: the results indicate that the long-term mean levels of hydrogen, sulfate, nitrate and calcium ion in the bulk (wet plus dry) precipitation samples were essentially constant. Use of the Box-Jenkins method was appropriate because samples that were collected close together in time were clearly more alike than those far apart, indicating autocorrelation. An analysis that fails to take this dependency into account could lead to incorrect conclusions. (Author's abstract)

ACID CLOUDS AND PRECIPITATION IN EASTERN COLORADO,
National Oceanic and Atmospheric Administration, Boulder, CO. Office of Weather Research and Modification.
C. T. Nagamoto, F. Parungo, R. Reinking, R. Pueschel, and T. Gerish.
Atmospheric Environment, Vol. 17, No. 6, p 1073-1082, 1983. 7 Fig, 3 Tab, 10 Ref.

Descriptors: *Clouds, *Acid rain, *Acid precipitation, Weather patterns, Snow. Hydrogen ion concentration, Seasonal variatic olorado, Denver.

Rain and snow samples were collected at the eastern foothills of the Rocky Mountains and analyzed for chemical composition. Many precipitation samples had pH values considerably more acidic than the 5.6 value of pure water containing only an equilibrium amount of atmospheric CO2. The averages of pH for rain and snow are 4.8 and 5.5, respectively. Approximately 80% of the snow samples show pH $>$ 5.5. Clear and considerable dependencies of the acidity on seasonal synoptic scale weather patterns are demonstrated. The most acidic snow or rain in winter is prefrontal or frontal precipitation derived from deep low-pressure centers tracking across or just to the south of Colorado. The most acidic summer precipitation occurs with patterns similar to these but weaker, and with synoptic conditions conducive to isolated but relatively deep convection. Cloud water samples, collected by aircraft over eastern Colorado, also showed low pH values. The acidity of clouds was greatest near the city of Denver. Samples collected over east Denver showed pH = 3.3, indicating that the city is a major source of the acid clouds in the area. Organic anions appeared in the samples taken near the city, but not in remote samples. (Moore-IVI)

MOVEMENT OF TYPHOID ORGANISMS IN SATURATED PERMEABLE SOIL,
Washington Univ., Seattle. School of Public Health and Community Medicine.
J. A. McGinnis, and F. DeWalle.
Journal of the American Water Works Association, Vol. 75, No. 6, p 266-271, June, 1983. 2 Fig, 3 Tab, 48 Ref.

Descriptors: *Typhoid fever, *Groundwater pollution, *Shallow wells, Septic tanks, Salmonella, Soil porosity, Saturated soils, Public health, Groundwater movement, Water table, Drinking water, Yakima, Washington.

An outbreak of typhoid fever occurred during May 1972 in Yakima County, Washington, involving groundwater transmission of Salmonella typhi between a septic tank and a nearby shallow well. The distance between the septic tank and the well was 64 m, greater that the 30-m separation considered safe sanitary practice for septic tank design in the state of Washington. Individual soil characteristics, the direction of groundwater flow, and the velocity of groundwater flow should be considered in planning a shallow well located down the hydrologic gradient from a leach field. In a high porosity soil, a 30-m separation is probably unsafe. Where highly porous soils and fluctuating water tables provide poor filtration of sewage effluent, as in the rural setting of the town of Yakima, chlorinated community potable water systems are safer than unchlorinated individual wells. HERBICIDE RUNOFF FROM EXPERIMENTAL WATERSHEDS,
Smithsonian Institution, Edgewater, MD. Chesapeake Bay Center for Environmental Studies.
T. L. Wu, D. L. Correll, and H. E. H. Remenapp.
Journal of Environmental Quality, Vol. 12, No. 3, p 330-336, July-September, 1983. 4 Fig, 4 Tab, 19 Ref. EPA grant R804536-01.

Descriptors: *Atrazine, *Alachlor, *Herbicides, *Water pollution sources, Nonpoint pollution sources, Path of pollutants, Agricultural runoff, Agricultural watersheds, Pesticide residues, Rhode River Watershed, Maryland.

Two commonly used herbicides in corn fields of the Rhode River Watershed (Maryland) were atrazine (2-chloro-4-ethylamino-6-iso-propylamino-1,3,5-triazine) and alachlor (2-chloro-2',6'-diethyl-N-methoxymethyl acetanilide). Although alachlor was applied in larger quantities, atrazine was detected more frequently in runoff waters and had greater concentrations than alachlor (0-4 micro g/L vs. 0-6 micro g/L). Atrazine was more persistent and more mobile in watershed soils. Linear regression analysis of herbicide loading rates and percentage agricultural landuse did not give a direct relationship. Runoff waters from forest watersheds where herbicides were not directly applied, were contaminated with herbicides. During the 3-y study period (1976-1978), a maximum of 10 micro g/L of atrazine, and up to 0.5 micro g/L alachlor were discharged in winter runoff waters from the eight experimental watersheds. In addition to quantity of herbicides directly applied to land surface, residual levels in runoff waters must be influenced by other important factors such as topography, location of croplands in relationship to drainage channel, etc. A major portion of atrazine was found in dissolved aqueous form in runoff-water samples collected during storm events. Percolation in subsurface flow and dissolution in overland flow were believed to be important transport mechanisms. (Author's abstract)

Descriptors: *Grazing, *Pasture management, *Water pollution sources, *Cattle, Agricultural runoff, Agricultural watersheds, Nonpoint pollution sources, Storm seepage, Nitrogen, Fertilizers, Nitrates, Ohio.

A beef cattle-pasturing system involving four rotationally grazed summer pastures (SG) and four pastures used rotationally for winter grazing/feeding (WGF) was studied on sloping upland watersheds in Ohio to determine effects of livestock management on N levels in water. Both summer and winter areas annually received 224 kg N/ha as NH4NO3 fertilizer. Surface runoff was collected automatically during runoff events, and subsurface flow was sampled from spring developments on a weekly basis. Although seasonal N concentration and transport in surface runoff tended to be greater in the area occupied by the cattle, N concentration and transport in runoff from the two areas were quite similar and did not significantly impair water quality, based on U.S. Public Health Standards. The NO3-N concentration in the subsurface flow from the WGF area was higher than in the subsurface flow from the SG area. The NO3-N concentration in the subsurface flow from both areas increased progressively throughout the study period, and reached levels as high as 18 mg/L. The subsurface flow provided the main pathway for N transport, with the surface transport being approximately 20 and 14% of the total N transport from the SG and WGF areas, respectively. The amount of sediment-N transported was very small because of low soil loss. (Author's abstract)

STREAM WATER QUALITY OF TWO SMALL WATERSHEDS AS AFFECTED BY SURFACE COAL MINING,
Ohio Agricultural Research and Development Center, Wooster.
W. A. Dick, J. V. Bonta, F. Haghiri, and J. R. Page.
Journal of Environmental Quality, Vol. 12, No. 3, p 351-358, July-September, 1983. 5 Fig, 8 Tab, 16 Ref. BM contracts J0166054 and J0166055.

Descriptors: *Coal mines, *Strip mines, *Water pollution sources, Water quality, Land reclamation, Suspended solids, Manganese, Hydrogen ion concentration, Flow rate, Heavy metals, Ohio.

Two small watersheds in eastcentral Ohio were selected for investigation of stream water quality prior to, during, and after surface coal mining and reclamation. Watershed C06 contained sandstone and shale overburden, and Watershed M09 contained limestone, sandstone, and shale. Water quality was monitored by measuring 39 parameters in the stream-water samples collected. Duration curves for the four parameters regulated by the Office of Surface Mining (OSM) showed that most samples collected from the two study watersheds exceeded the 70 mg/L regulation level for suspended solids concentration. Approximately 50 and 30% of the water samples collected at Watershed C06 during the mining and reclamation period and the post-reclamation period, respectively, exceeded the regulation level (4000 micro g/L) for manganese (MN). Twenty percent of the pH values at Watershed C06 during the mining and reclamation period were also below the lower regulation level (pH 6). Concentrations of the major cations and anions, suspended solids, and dissolved solids were correlated with flow rate (log values) during the premine and post-reclamation periods. Samples collected at similar flow rates at Watershed M09 showed concentrations of parameters were either not significantly affected or decreased in the post-reclamation samples, compared with the premine samples. A similar comparison for samples collected at the C06 watershed showed parameter concentrations were generally higher during the post-reclamation period. Parameters which were not detected in any samples collected from the two watersheds were arsenic (As), chromium (Cr) VI, mercury (Hg), and sulfide (S(2-)), while cyanide (CN(-)) was not detected at M09. Parameters that were only rarely detected were antimony (Sb), cadmium (Cd), lead (Pb), zinc (Zn), silver (Ag), copper (Cu), phenols, and phosphorus (P). (Author's abstract)

PCB PARTITIONING IN SEDIMENT-WATER SYSTEMS: THE EFFECT OF SEDIMENT CONCENTRATION,
Manhattan Coll., Bronx, NY. Environmental Engineering and Science Program.
L. M. Horzempa, and D. M. Di Toro.
Journal of Environmental Quality, Vol. 12, No. 3, p 373-380, July-September, 1983. 12 Fig, 3 Tab, 24 Ref.

Descriptors: *Polychlorinated biphenyls, *Sediments, *Sorption, Montmorillonite, Partition coefficients, Adsorption isotherms, Fate of pollutants, Lake sediments, Suspended particulates, Saginaw Bay, Michigan.

The effect of sediment concentration variations on polychlorinated biphenyl (PCB) sorption to natural lake sediment (Saginaw Bay, Mich.) and montmorillonite clay has been investigated. In studies utilizing tritiated 2,4,5,2',4',5'hexachlorobiphenyl (HCBP), partition coefficient values for adsorption isotherms (pi) were found to increase as sediment concentrations (m) were decreased from m = 1000 mg/L to m = 50 mg/L. HCBP adsorption to montmorillonite (m = 1000 mg/L, pi = 2900 L/kg; m = 50 mg/L, pi = 10 600 L/kg) appeared to be more sensitive to sediment concentration than did adsorption to the Saginaw Bay sediment (m = 1000 mg/L, pi = 9900 L/kg; m = 50 mg/L, pi = 17,100 L/kg). Evidence suggests that these variations are not the result of nonlinear isotherms. Although variations in solution chemical composition and kinetic effects were found to affect partitioning, neither factor appeared to adequately account for the magnitude of the observed sediment concentration effect. In experiments in which sediment concentrations were decreased (m = 1000 mg/L to 10 mg/L) while equilibrium aqueous HCBP concentrations were maintained at approximately constant levels, pi values for adsorption increased. The behavior was in conformity with the isotherm results. The observed behavior might be due to direct solid phase interactions between suspended particles. The occurrence of such interactions in natural waters could have potentially significant implications for efforts to predict sediment-water PCB distributions. (Author's abstract)

LOSS OF FALL-APPLIED 2,4-D IN SPRING RUNOFF FROM A SMALL AGRICULTURAL WATERSHED,
Department of Agriculture, Swift Current (Saskatchewan). Research Station.
W. Nicholaichuk, and R. Grover.
Journal of Environmental Quality, Vol. 12, No. 3, p 412-414, July-September, 1983. 1 Tab, 11 Ref.

Descriptors: *Herbicides, *Snowmelt, *Agricultural runoff, Surface runoff, Water pollution sources, Nonpoint pollution sources, Pesticide residues, Wheat, Saskatchewan.

The loss of 2,4-D (2,4-dichlorophenoxyacetic acid) applied in fall to wheat (Triticum aestivum L.) stubble on fields of Wood Mountain loam soil in semiarid southwestern Saskatchewan was measured in surface runoff from snow. The range of runoff volumes over the 6-y period was representative of runoff observed over a 30-y period at the same location. The loss of 2,4-D was greater from the treated stubble compared with fallow, which served as the control. The average loss from the control of 1.3 g/ha gives an indication of background limits that can be expected if 2,4 applied a year earlier. The 2,4-D loss in sno runoff is similar to losses in rainfall runoff severe storm soon after application. The 6-y age loss was 4.1% of the amount applied (0. ha). Correlation analysis showed that amo loss to be a function of runoff. The average weighted mean concentration of 31 micro g/ well below the USEPA maximum permissibl of 100 micro g/L, and slightly above the National Academy of Sciences and National emy of Engineering objective of 20 micro g drinking-water standards. Microbiological surveys of untreated wa service reservoirs in Strathclyde Regions in land revealed a deterioration in bacterial q during storage. In a three-year study the s reservoirs supplying Loch Katrine water to gow were shown to be contaminated by (Larus sp) nocturnally roosting on the reservo winter. Significant correlations were mad tween the number of roosting gulls and the bers of E. coli present in the untreated res water. In addition, similar salmonellae orga of identical serotypes were isolated from the the untreated water and, on three occasions, the treated water. Occlusion of bacteria by pa late avian fecal matter rendered marginal chl tion of up to 0.2 ml/l of free chlorine re ineffective. Subsequently, the routine broadc by loud speaker of species specific distress c Larus gulls proved to be effective in discour gulls from roosting on the reservoirs. The pearance of the gulls resulted in improved quality. Water in the reservoirs at Helens was also found to suffer deterioration in bac quality during storage. These reservoirs were ied over a three-month period to compar effect of diurnal and nocturnal gull populatio water quality. Limited scaring was attempt this site, and the results showed favorable imp ments in water quality. (Baker-IVI)

Descriptors: *Polychlorinated biphenyls, * *Industrial wastes, Ships, Water pollution so Bioaccumulation, Japan, Nagasaki Bay.

Polychlorinated biphenyl (PCB) concentra were determined in sediment, in water, a biological samples from Nagasaki Bay, J PCBs were detected in all samples, with hi concentrations more than 10 micrograms/g, found in three sediment samples located nea shipyard drains. In general, PCB concentratio sediments and organisms tended to increase to the inner part of this bay. PCB isomer and c ner compositions in organisms as well as sedi were composed mainly of higher chlorinate phenyls and almost similar to Kanechlor 50 600 products (chlorine content 54 and 60% spectively) that have been used for ship p These results strongly suggest that shipbuildi primarily responsible for the PCB pollution i

ki Bay. Bioaccumulation factors of PCBs were erent among the organisms according to their hic levels. This might be a result of the pre-inant PCB transfer through the food chain in nisms and the discharge of bioaccumulative s as higher chlorinated biphenyls from ship-s. The PCB pollution from shipbuilding may inue for a long time due to the accumulative acteristics of PCBs used for ship paints and the ier discharge by scraping the old paints in yards. (Baker-IVI)

riptors: *Polychlorinated biphenyls, *Adsorp-*Desorption, *Lake sediments, Fate of pollut-Montmorillonite, Kaolinite, Clay, Isotherms, chlorobiphenyl, Partition coefficients, Sedi-, Michigan, Lake Huron, Saginaw Bay.

xtent of reversibility of PCB (polychlorinat-phenyl) bonding to sediments has been char-zed in studies on the partitioning behavior of achlorobiphenyl isomer. Linear non-singular rms have been observed for the adsorption lesorption of 2,4,5,2'4',5' hexachlorobiphenyl P) to 1100 ppm sediment suspensions. Parti-oefficients, pi(1/kg), for desorption from lake ents (Saginaw Bay, Lake Huron, Michigan) ubstantially greater (pi sub d about 20,000-35,000) than those obtained for adsorption (pi sub a about 9000-14000). HCBP was found to be more weakly adsorbed to montmorillonite (pi sub a about 3000, pi sub d about 9000) and kaolinite (pi sub a about 1000, pi sub d about 3000) clay samples than to the natural sediment samples. Desorption results (pi sub d) for Saginaw Bay sediments were quite similar to pi values (15,000-35,000) calculated from field measurements of aqueous and particulate PCB concentrations. For Saginaw Bay sediments and clay minerals partitioning appeared to be correlated both to sediment surface area and to sediment organic content. A regression analysis using both of these variables explained approximately 90% of the observed variations. HCBP adsorption at 40 degrees C (pi sub a about 14,000) was significantly greater than at 1 degree C (pi sub a about 6500) resulting in a calculated enthalpy of adsorption of +3.3 kcal/mol. Non-singular isotherm behavior was not found to be readily attributable to microbiological, kinetic or experimental effects. Evidence from consecutive desorption studies suggests that while HCBP adsorption may ultimately be reversible, release from sediments appeared to involve desorption along two distinct isotherms. These results have been interpreted in terms of possible similarities between the sorption properties observed in the distilled water systems of the present study and PCB bonding processes in natural water systems. STREAM WASTE ASSIMILATIVE CAPACITY ANALYSIS USING REAERATION COEFFICIENTS MEASURED BY TRACER TECHNIQUES,
Hawaii Univ., Honolulu. Dept. of Civil Engineering.
C. C. K. Liu, and Y-S. Fok.
Water Resources Bulletin, Vol. 19, No. 3, p 439-445, June, 1983. 6 Fig, 4 Tab, 19 Ref.

Descriptors: *Assimilative capacity, *Reaeration, *Gas tracers, Tracers, Aeration, Water quality, Model studies, Canandaiqua Outlet, New York.

Atmospheric reaeration is one of the most important natural processes which determine the waste assimilative capacity of a receiving water. Values of reaeration coefficient used in the receiving water modeling analysis strongly influence the allowable wastewater treatment levels of potential point sources discharging into this water. Stream water quality models are developed with reaeration coefficients (K2) estimated by predictive equations, which leads to uncertainties in modeling analysis because these equations are empirical in nature and may yield greatly different K2 values for the same stream. The validity of a stream model would be enhanced significantly if K2 could be determined directly and reliably. Values of K2 in the Canandaiqua Outlet in Central New York have been measured by using a gas tracer method. A successful modeling analysis was conducted using these K2 values. As a result, effluent limitations of several waste water discharges into the Outlet were established. Field measurements of reaeration rate would improve modeling results significantly, and the gas tracer method can be easily incorporated into intensive water quality surveys normally required for stream modeling. DYNAMIC BACTERIAL MODEL FOR A RECREATIONAL LAKE,
Cook Coll., New Brunswick, NJ. Dept. of Environmental Sciences.
C. G. Uchrin, and W. J. Weber, Jr.
Water Resources Bulletin, Vol. 19, No. 4, p 581-584, August, 1983. 5 Fig, 7 Ref.

Descriptors: *Bacteria, *Water pollution sources, *Fate of pollutants, Mathematical models, Simulation, Storm runoff, Wastewater, Reservoirs, Nonpoint source pollution, Ford Lake, Michigan.

A dynamic mathematical model was constructed to examine bacterial contamination problems affecting Ford Lake, a small recreational lake in Southeast Michigan. Ford Lake is a Huron River impoundment resulting from backwater caused by Ford Dam. The model was calibrated and verified using summer dry weather averaged data and data from three wet weather surveys. Model simulations demonstrated that the major bacterial contamination was attributable to storm related perturbations affecting two point sources: the Huron River and the Ypsilanti Sewage Treatment Plan. The nonpoint source contribution was relatively minor. Ford Lake serves as an effective bacteriological sink for pollutant loadings from point and nonpoint source inputs. Most of the resultant stress is confined to the upstream segments of the lake. The lake generally reverts to dry weather, steady state conditions within a week. Even under worst cases the lake exhibits negligible bacterial impact downstream. The model is currently being used by the State of Michigan Department of Natural Resources as a management tool by assessing the effectiveness of planned pollution abatement strategies. (Moore-IVI)

MODELING GROUND-WATER FLOW AT LOVE CANAL, NEW YORK,
GeoTrans, Inc., Reston, VA.
J. W. Mercer, L. R. Silka, and C. R. Faust.
Journal of Environmental Engineering, Vol. 109, No. 4, p 924-942, August, 1983. 7 Fig, 3 Tab, 17 Ref.

Descriptors: *Groundwater movement, *Path of pollutants, *Love Canal, New York, Geohydrology, Computer models, Lockport Dolomite, Interceptor wells, Water pollution control, Groundwater pollution.

A ground-water modeling study was conducted at the Love Canal area, Niagara Falls, New York, as part of a comprehensive evaluation of contamination at the area. The hydrogeology underlying Love Canal consists of a shallow system of silts and fine sands, underlain by confining layers of lacustrine clays and glacial till, which are underlain by the Lockport Dolomite. A two-dimensional computer model of the Lockport Dolomite was constructed to help define the ground-water flow system. Both history matching and a sensitivity analysis were conducted. Assuming the dolomite was contaminated, Monte Carlo simulation and uncertainty analysis were used to estimate contaminant travel times to the upper Niagara River. Results indicate that travel times would average 1,000 days with less than 5% probability of less than 100 days or greater than 10,000 days. Analysis of remedial action for the Lockport Dolomite using best estimates of hydrologic parameters indicates that three interceptor wells at the south end of the canal, pumped at only 1,155 cu ft/day (32.3 cu m/day), should reverse the flow of ground water to the river and provide an adequate barrier to migration of potential contaminants to the river. ANTHROPOGENIC ZINC AND CADMIUM BURDENS IN SEDIMENTS OF SELECTED SOUTHERN ONTARIO LAKES,
Trent Univ., Peterborough (Ontario).
H. E. Evans, P. J. Smith, and P. J. Dillon.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 5, p 570-579, May, 1983. 3 Fig, 4 Tab, 44 Ref.

Descriptors: *Cadmium, *Zinc, *Lake sediments, Lead, Heavy metals, Water pollution sources, Watershed area, Replenishment, Atmosphere, Ontario.

The concentrations of Cd and Zn were measured in the sediments of 10 softwater lakes in southern Ontario. Elevated Cd and Zn levels were present in the recently deposited sediments of all the lakes, despite the absence of local point-source inputs. Whole-lake anthropogenic Zn and Cd burdens, calculated by prorating site-specific burdens according to the ratio of the site-specific Pb burden to the whole-lake Pb burden, range between 322 and 617 mg/sq m for Zn and between 6.2 and 11.3 mg/sq m for Cd. There were no significant differences in anthropogenic Zn or Cd burdens between

LIBRARY U. OF I. URBANA-CHAMPAIGN

lakes. The lack of a relationship between Zn or Cd burdens and the ratio of watershed area to lake area or the water replenishment time of the lakes indicates that deposition from the atmosphere directly onto the lakes surfaces is an important input of these metals to the lakes. (Author's abstract)

Descriptors: *Water pollution sources, *Atmospheric deposition, *Oligotrophic lakes, *Sulfur, Forest watersheds, Ammonia, Nitrates, Chloride, Alkalinity, New York, Panther Lake, Woods Lake, Sagamore Lake.

Three watershed-lake systems of the Integrated Lake-Watershed Acidification Study (ILWAS) were investigated to determine the effects of atmospheric deposition on the chemical compositions of oligotrophic lakes. Panther, Woods, and Sagamore lakes are in the Adirondack State Park, New York. The watersheds are forested with a mixture of hard and soft woods and have areas of 1.24, 2.07, amd 49.7 sq km, respectively. Annually, about 90% of the NH4(+) and 50% of the NO3(-) from atmospheric deposition were retained in the systems. In the Woods system, Cl(-) was in steady state with respect to atmospheric deposition although both Panther and Sagamore systems had net losses, indicating watershed sources of Cl(-). The losses of base cations from Panther and Sagamore were substantially greater than from the Woods system, reflecting the shallow soils of the latter. The concentrations of SO4(2-) in the waters of the three systems were controlled by the atmospheric deposition of anthropogenic sulfur; in Woods and Panther, inputs (atmospheric deposition) equalled outputs (discharges from the lake outlets); in Sagamore, outputs exceeded inputs. In 1978-80, concentrations of SO4(2-) were four to five times higher than historical values. These increased concentrations had caused either decreased alkalinities of surface waters or increased concentrations of base cations or both. Decreased alkalinity directly affects aquatic ecosystems; increased concentrations of base cations directly affect terrestrial ecosystems because of increased rates of loss of the nutrients Ca, Mg, and K in the absence of resupply from primary weathering. INFLUENCE OF SEWAGE TREATMENT AND URBANIZATION ON SELECTION OF MULTIPLE RESISTANCE IN FECAL COLIFORM POPULATIONS,
Oxoid Canada, Inc., Nepean (Ontario).
J. B. Bell, G. E. Elliott, and D. W. Smith.
Applied and Environmental Microbiology, Vol. 46, No. 1, p 227-232, July, 1983. 6 Tab, 25 Ref.

Descriptors: *Coliforms, *Antibiotic resistance, *Wastewater treatment, Wastewater lagoons, Fecal coliforms, Urban areas, R factors, Effluents, Water quality, Wastewater management, Slave River, Red River, Canada.

The fecal coliform populations found in the raw sewages and final sewage effluents of mechanical treatment plants, a long-term retention lagoon, shorter-term retention lagoons, a remote northern Canada river, and a heavily urbanized prairie river were examined for antibiotic resistance and the possession of R factors. It was determined that there was a decrease in the percentage of multiresistant fecal coliform populations in the mechanical sewage treatment plants and shorter-term retention lagoons; however, there was an increase in populations from the long-term retention lagoon. The percentage of the populations possessing transmissible R factors was constant in the mechanical treatment and shorter-term retention facilities; however, the ability to transmit was lost in 50% of the infective population of the long-term retention facility. A striking contrast was found between the populations of the remote northern Slave River and those of the urbanized Red River. Of the fecal coliforms in the Slave River, 7.1% were multiresistant, and only 0.79% possessed transmissible R factors. The Red River fecal coliform populations were 52.9% multiresistant, and 18.77% of the total population possessed transmissible R factors. The influence of urbanization and the type of sewage treatment have been shown to affect the selection and survival of multiresistant fecal coliforms and R+ fecal coliforms. Determination of other factors influencing the development and the survival of these populations is needed for rational wastewater management and water quality consideration. (Author's abstract)

DEGRADATION AND TOTAL MINERALIZATION OF MONOHALOGENATED BIPHENYLS IN NATURAL SEDIMENT AND MIXED BACTERIAL CULTURE,
Tennessee Univ., Knoxville. Dept. of Microbiology.
H.-L. Kong, and G. S. Sayler.
Applied and Environmental Microbiology, Vol. 46, No. 3, p 666-672, September, 1983. 6 Fig, 3 Tab, 18 Ref. EPA grant R808457010.

Descriptors: *Monohalogenated biphenyls, *Bacteria, *Biodegradation, Degradation products, Mineralization, Polychlorinated biphenyls, River sediments, Water pollution effects, Solar radiation.

Mixed bacterial cultures obtained from polychlorinated biphenyl-contaminated river sediments are capable of degrading monohalogenated biphenyls under simulated natural conditions. Culture conditions include river water as supportive medium and mixed bacterial cultures obtained from river sediments. Degradation occurs when the substrates are supplied as the sole carbon source or when added together with glucose. The degradation rates of 2-, 3-, and 4-chlorobiphenyl, at 30 micro g/ml, were 1.1, 1.6, and 2.0 micro g/ml/day, respectively. Monobrominated biphenyls, including 2-, 3-, and 4-bromobiphenyl, were degraded at rates of 2.3, 4.2, and 1jIicro g/ml/day, respectively. Metabolites, including halogenated benzoates, were detected by high-performance liquid chromatography and mass spectrometry. By using chlorophenyl ring-labeled monochlorobiphenyls as substrates, total mineralization (defined as CO2 production from the chlorophenyl ring) was observed for 4-chlorobiphenyl but not for 2-chlorobiphenyl. Rates of total mineralization of 4-chlorobiphenyl (at 39 to 385 micro g/ml levels) were dependent on substrate concentration, whereas variation of cell number in the range of 105 to 107 cells/ml had no significant effects. Simulated sunlight enhanced the rate of mineralization by ca. 400%. (Author's abstract)

Descriptors: *Reservoirs, *Detention time, *Mathematical models, Chloride, Tracers, Water quality.

A mathematical model is presented for the determination of the detention characteristics of river impoundments. The time dependent concentration of a naturally available, perseverant substance (chloride) being measured at the inlet and the outlet of an impoundment served as a tracer. Since the addition of a strange tracer substance is not necessary, all possible problems to be considered with such procedures do not occur. The method was successfully applied at the Ruhr impoundment 'Baldeneysee'. The results were most useful for the interpretation of observed water quality proce

effects of superphosphate (50 kg P/ha), ap-
as a liquid or a solid, on transport of dis-
d and particulate P in surface runoff from
ished pasture were evaluated using field plots
atural rainfall. An approximately 3-fold in-
e in the transport of both dissolved inorganic
particulate P in surface runoff was measured
weeks following fertilizer application in the
form (2.9 and 2.9% of the applied fertilizer P,
ctively) compared to the liquid application
nd 1.1% of the applied fertilizer P, respec-
). The application of solid fertilizer P has a
sustained effect on the concentration of both
ved and particulate P in surface runoff. The
ntration of particulate P had not returned to
refertilizer levels some 16 weeks after the
ation of solid P. Although the application of
fertilizer P reduced losses of P in surface
f from pasture compared to a solid applica-
he agronomic effectiveness of the two forms
be considered. Since solid fertilizer is more
ive on pasture than liquid fertilizer (on an
cost basis), the use of liquid fertilizer may
e an economic method of reducing P trans-
n runoff from agricultural land which has a
P-loading potential. (Moore-IVI)

5C. Effects Of Pollution

TOXICITY OF SELECTED PRIORITY POLLUTANTS TO VARIOUS AQUATIC ORGANISMS,
Environmental Research Lab.-Duluth, MN.
G. W. Holcombe, G. L. Phipps, and J. T. Fiandt.
Ecotoxicology and Environmental Safety, Vol. 7, No. 4, p 400-409, August, 1983. 4 Tab, 18 Ref.

Descriptors: *Toxicity, *Organic compounds, *Aquatic populations, Enviromental effects, Water pollution effects, Acenaphthene, Arsenic trioxide, Cadmium chloride, Mercury chloride, Silver nitrate, Chlordane, Endosulfan, Heptachlor, Pesticides, Fish.

Toxicity tests were conducted with selected compounds listed by the United States Environmental Protection Agency as priority pollutants. Acute toxicity information was determined for acenaphthene, arsenic trioxide, cadmium chloride, mercury (II) chloride, silver nitrate, chlordane, endosulfan, and heptachlor. Acute tests were conducted using one or more of the following species: fathead minnows (Pimephales promelas), channel catfish (Ictalurus punctatus), rainbow trout (Salmo gairdneri), brown trout (Salmo trutta), brook trout (Salvelinus fontinalis), bluegills (Lepomis macrochirus), snails (Aplexa hypnorum), or chironomids (Tanytarsus dissimilis). Acute values from these tests ranged from a silver nitrate 96-hr median of 6.7 micrograms/liter for fathead minnows to an arsenic trioxide 48-hr lethal dose of 97,000 micrograms/liter for chironomids. In addition to acute tests, a fathead minnow embryo-larval exposure was conducted with silver nitrate to estimate chronic toxicity. The estimated maximum acceptable toxicant concentration for silver nitrate, based on fathead minnow survival, lies between 0.37 and 0.65 micrograms/liter. (Author's abstract).

HISTOLOGICAL OBSERVATIONS IN GILLS OF THE TELEOST SAROTHERODON MOSSAMBICUS WITH REFERENCE TO MERCURY TOXICITY,
Sri Venkateswara Univ., Tirupati (India). Dept. of Zoology.
K. A. Naidu, K. A. Naidu, and R. Ramamurthi.
Ecotoxicology and Environmental Safety, Vol. 7, No. 5, p 455-462, October, 1983. 12 Fig, 9 Ref.

Descriptors: *Mercury, *Toxicity, Histology, Pesticides, Mercury chloride, Industrial wastes, Water pollution effects, Environmental effects.

Histological changes in the gills of Sarotherodon mossambicus exposed to lethal and sublethal concentrations of mercuric chloride were recorded. The characteristics of the test medium (tap water) were: pH 7.0-7.3; alkalinity 9.7 ppm of CaCO3; dissolved oxygen 5.3-6.2 mg/liter; hardness 35 ppm of CaCO3; and temperature 28-32 degrees C. The first group was exposed to 1.5 ppm of mercuric chloride, while the second, third, and fourth groups were exposed to 0.1 ppm of mercuric chloride for 1, 15, and 30 days, respectively. Gross structure of gill filaments appeared normal. Microscopic changes were noted in secondary gill lamellae and interlamellar cells of exposed fish. In the lethal exposure group the secondary gill lamellae were enlarged into bulb-like structures. These bulgings were notes at distal and basal portions of the lamellae. Some of the lamellae were collapsed. Necrosis and desquamation of the lamellae were also noted. In sublethal exposure after one day, in addition to bulgings at the tips of the lamellae, there were hypertrophy and hyperplasia of lamellar and interlamellar cells. In 15-day exposed fish, separation of the epithelial layer of gill lamellae from pillar cells was the prominent feature. Blood spaces between pillar cells of the lamellae were empty. Such damage will probably affect the respiratory function of the gill by reducing respiratory surface area. (Baker-IVI)

RESTORATION OF NORWEGIAN LAKES BY REDUCTION IN SULPHUR DEPOSITION,
Norsk Inst. for Vannforskning, Oslo.
R. F. Wright, and A. Henriksen.
Nature, Vol. 305, No. 5933, p 422-424, September, 1983. 3 Fig, 13 Ref.

Descriptors: *Acid rain, *Fish Lakes, Acidity, Sulfur, Water pollution effects, Norway.

Acid precipitation, causing the acidification of freshwaters and hence damage to fisheries, affects more than 33,000 sq km of southern Norway. As a first step in dealing with the acidification problem, Norway, Sweden and Finland have proposed that emissions of sulfur in Europe be reduced by 30% by 1993. Using data from a 1974-75 survey of major-ion chemistry and fish populations in 683 lakes in southern Norway, a 30% reduction in sulfur deposition will restore chemical conditions such that 22% of the lakes now experiencing fisheries problems should be able to support fish. The method of prediction derives from empirical relationships between sulfur deposition, water chemistry and fisheries status for several thousand lakes and rivers in Europe and North America. The method takes into account lake-to-lake differences in sensitivity, changes in base cation concentrations, and the buffering of dissolved aluminium at pH readings less than 5.4 and of bicarbonate at pH levels greater than 5.4. (Baker-IVI)

OCCURRENCE OF SOME INDICATOR BACTERIA IN THE WATERS OF AL-KHAIR STREAM, AND AL-JAISH CANAL PASSING THROUGH BAGHDAD CITY,
Biological Research Center, Baghdad (Iraq). Dept. of Environmental Pollution.
S. F. Jazrawi, and M. W. Ishaq.
Journal of Environmental Science and Health, Vol. A18, No. 5, p 673-684, September, 1983. 1 Fig, 3 Tab, 11 Ref.

Descriptors: *Bacteria, *Water quality, *Coliforms, Fecal coliforms, Streptococci, Baghdad, Iraq, Domestic waste.

Water samples were collected from twelve stations located in two water sources in Baghdad city. Samples were monitored for total aerobic bacteria, total coliforms, fecal coliforms and fecal streptococci. Samples were collected monthly from December of 1980 to December of 1981. High counts of pollution indicator were observed at all stations studied and were distributed independently of temperature, pH, and chloride concentration of the water samples. Total bacteria numbered from 2000 to 9000/ml in Al-Khair stream water and 2000 to 6000 m/l in the water of Al-Jaish canal. The population of total coliforms in the water of Al-Khair stream varied between 1000 and 4000/100 ml and that of fecal coliforms was between 0 and 3000/100 ml. Whereas the number of total coliforms and fecal coliforms in the water of Al-Jaish canal varied from 1000 to 55000/100 ml and from 0 to 100000/100 ml respectively. Numbers of total and fecal coliforms were highest in December which may be associated with the heavy rainfall which occurred within 24 hrs of sampling. Fecal streptococci were present mainly in lower amounts than the fecal coliforms in water samples. The constant presence of the indicator organisms in the samples

was due to the fact that there is continuous discharge of untreated domestic wastes in these two water sources. No periodic self purification was observed in the waters of these sources. Therefore, these water sources are not suitable for public water supplies, swimming, or recreational purposes. (Baker-IVI)

CONTAMINATION OF A MAJOR WATER SUPPLY BY GULLS (LARUS SP.); A STUDY OF THE PROBLEM AND REMEDIAL ACTION TAKEN,
Strathclyde Regional Council, Glasgow (Scotland). Water Dept.
C. Benton, F. Khan, P. Monaghan, W. N. Richards, and C. B. Shedden.
Water Research, Vol. 17, No. 7, p 789-798, 1983. 5 Fig, 4 Tab, 23 Ref.

Descriptors: *Water pollution sources, *Storage reservoirs, *Gulls, *Coliforms, Bacteria, Water pollution prevention, Salmonella, Water supply, Scotland, Glasgow.

In recent years one of the storage reservoirs supplying Loch Katrine water to Glasgow exhibited a serious deterioration in bacterial quality. This was associated with the winter nocturnal roosting habits of gulls (Larus sp.) on the reservoir. Investigations showed a significant correlation between the number of gulls roosting and the numbers of E. coli present in the water. Salmonellae organisms of identical serotypes were isolated from the gulls, from the untreated water and, on three occasions, from the treated water. Broadcasting species specific distress calls of Larus gulls proved to be an effective measure for discouraging gulls from roosting on the reservoir. The routine use of this bio-acoustic method of gull scaring reduced the bacteria in the water to numbers typical of an upland unpolluted reservoir. (Author's abstract)

EFFECT OF ACIDIFICATION, METALS AND METALLOIDS ON SEDIMENT MICROORGANISMS,
Waterloo Univ. (Ontario). Dept. of Biology.
M. D. Baker, W. E. Inniss, C. I. Mayfield, and P. T. S. Wong.
Water Research, Vol. 17, No. 8, p 925-930, 1983. 4 Fig, 1 Tab, 21 Ref.

Descriptors: *Lake sediments, *Hydrogen ion concentration, *Microorganisms, *Decomposition, *Metals, *Metalloids, Water temperature, Lead, Mercury, Arsenic, Selenium, Toxicity, Bacteria, Ontario, Plastic Lake.

Using sediment from Plastic Lake near Dorset, Ontario, the effects of pH changes, metals and metalloids on sediment microorganisms were studied. The mineralization of C-14 glucose was reduced in sediments of pH 4 and 5 compared to pH 7. A large reduction in glucose mineralization was also observed at low temperature (0 degrees C). The majority of bacterial isolates recovered at incubation temperatures of 0 and 20 degrees C were psychrotrophic and the majority of both populations was resistant to lead and selenium while a smaller proportion was resistant to mercury and arsenic. Many of the bacteria were resistant to more than one of the elements. Lead and mercury were more toxic to bacterial growth at pH 4.5 than at 7.5, while selenium and arsenic were slightly more toxic at the higher pH values. The reduction in microbial activity may explain the observed accumulation of organic matter in some acidic lakes. Another factor in such accumulations may be the increase in metal and metalloid concentrations under low pH conditions. (Moore-IVI)

EFFECT OF AN INDUSTRIAL AMMONIA DISCHARGE ON THE DISSOLVED OXYGEN REGIME OF THE WILLAMETTE RIVER, OREGON,
Oregon State Dept. of Environmental Quality, Portland
D. A. Dunnette, and R. M. Avedovech.
Water Research, Vol. 17, No. 9, p 997-1007, 1983. 5 Fig, 6 Tab, 41 Ref.

Descriptors: *Ammonia, *Nitrification, *Water pollution effects, *Dissolved oxygen, *Willamette River, Oregon, Industrial wastewater, Bacteria, Simulation, Computer models, Nitrates.

An industrial discharge of 7000-10,000 kg/day ammonia nitrogen can exert a very great impact on the oxygen regime of the lower Willamette River, Oregon through the microbially mediated process of nitrification. This conclusion is based upon the following evidence: inorganic nitrogen mass flow data; measured reductions in Willamette River dissolved oxygen during ammonia discharge as compared to non-discharge conditions; the present of nitrifying bacteria in mud and attached to aquatic vegetation and river cobbles; verification of a dissolved oxygen model based upon nitrification as a primary ammonia sink and a dominant deoxygenation process; and N-15 heavy isotope tracer studies indicating significant conversion of ammonia to nitrate. Chemical evidence indicates and a dissolved oxygen computer simulation model verifies that a reduction of approximately 50% in as industrial ammonia discharge of several metric tons per day was the major factor in a dissolved oxygen increase of 15% on the lower Willamette River between 1973 and 1979. A shallow, fast flowing, highly surface active and ammonia enriched reach of the river was identified as a reach of high impact active nitrification. In an actively nitrifying reach of the Willamette River a gradual increase in nitrate nitrogen from 0.2 to 0.4 mg/l was observed in a distance of about 53 km. Based on a flow rate of 184 cu m/s this is equivalent to about 3180 kg of ammonia nitrogen nitrified per day in this reach assuming no additional nitrate sources or sinks. (Moore-IVI)

ASSESSING AQUATIC PRODUCTIVITY IN THE HOUSATONIC RIVER USING THE ALGAL ASSAY: BOTTLE TEST,
Massachusetts Univ., Amherst. Dept. of Civil Engineering.
N. M. Ram, and S. Plotkin.
Water Research, Vol. 17, No. 9, p 1095-1106, 1983. 6 Fig, 5 Tab, 32 Ref.

Descriptors: *Eutrophication, *Productivity, *Algae, *Water pollution effects, *Housatonic River, Connecticut, Massachusetts, Phosphorus, Nitrogen, Nutrients, Phosphorus removal, Wastewater treatment, Effluent.

Dense algal growth and large diurnal oxygen variations in both free flowing and impounded reaches of the Housatonic River in Connecticut and Massachusetts prompted a concentrated study to assess the need for a comprehensive basin wide phosphorus abatement program and the contribution of point source discharges to eutrophication of the river. Inorganic nutrient levels and bioassay data indicated a predominance of nitrogen limitation below Pittsfield, MA resulting from discharges of phosphorus-rich, municipal and industrial wastewater into the river. N:P ratios suggested that the nutrient status of the river varied, to some extent, even over as short an interval as 2 months and was probably attributable to flow variations in the river. Algal assays of water samples confirmed the nutrient limitation predicted by N:P ratios in 10 out of 13 cases. Additions of varying percentages of untreated, and alum-treated Pittsfield domestic wastewater treatment plant effluent to Housatonic River water, resulted in a linear increase in algal yield that was within 20% of values predicted by inorganic nutrient content. No significant reduction in algal growth response was observed, however, in the alum-treated sewage since its N:P ratio was not sufficiently shifted to phosphorus limitation after 66% phosphorus removal (Al:P equal to 1.3:1). Phosphorus removal at Best Practicable Technology levels would therefore probably not change the nutrient status of the Pittsfield wastewater to phosphorus limitation. (Author's abstract)

ACUTE TOXICITY OF PICRIC ACID AND P RAMIC ACID TO RAINBOW TROUT SAL GAIRDNERI, AND AMERICAN OYST CRASSOSTREA VIRGINICA,
Johns Hopkins Univ., Shady Side, MD. Aqu Ecology Section.
W. L. Goodfellow, Jr., D. T. Burton, W. C. Graves, L. W. Hall, Jr., and K. R. Cooper.
Water Resources Bulletin, Vol. 19, No. 4, p 6 648, August, 1983. 2 Fig, 4 Tab, 38 Ref. Ar grant ARMY M1PR 2506.

Descriptors: *Picric acid, *Picramic acid, *Tox ty, *Trout, *Oysters, Estuarine environment, S ment contamination, Water pollution effects, trophenols, Adsorption.

Picric acid (2,4,6-trinitrophenol) and picramic a (2-amino-4,6-dinitrophenol) are potential wa pollutents due to a variety of industrial and mu tion uses. The possible impacts of picric and p ramic acid to two recreationally and commercia important species, rainbow trout, Salmo gairdn and American oysters, Crassostra virginica, w evaluated. Picramic acid was more toxic th picric acid to both species tested. The 96-h LC for picric and picramic acids for rainbow tr were 109.6 and 46.2 mg/l, respectively. The 14 LC50s for picric and picramic acid for Ameri oysters were 254.9 and 69.8 mg/l, respective Sublethal no growth EC50s and shell deposit EC50s for oysters showed that both compou caused adverse effects at much lower concent tions than indicated by the LC50s. For examp the 144-h shell deposition EC50s were 27.9 m for picric acid and 5.6 mg/l for picramic ac Sediment adsorption studies in estuarine water dicated that both compounds are not readily sorbed which suggests that sediment would play a major role as a sink in contaminated s tems. Oysters, which filter large quantities of p ticulate matter, would more likely be affected picric and picramic acids in the water column th by exposure to contaminated sediment. (Autho abstract)

ONONDAGA LAKE AND DISSOLVE OXYGEN IN SENECA RIVER,
Upstate Freshwater Inst., Syracuse, NY.
S. W. Effler, P. Jaran, and C. F. Carter.
Journal of Environmental Engineering, Vol. 1 No. 4, p 945-951, August, 1983. 1 Fig, 1 Tab, Ref.

Descriptors: *Dissolved oxygen, *Lakes, Lake O ondaga, Seneca River, New York, Rivers, Phy plankton, Water pollution effects, Stratificati

The Seneca River is part of the Three Riv system, which drains more than 5,000 sq miles Central New York to Lake Ontario. There a indications that the source of ionic pollution to t lake, and the chemically-based stratification in t river, may be eliminated in the future. An evalu tion is presented, conducted by model simulati of the impacts the removal of chemical stratifi tion and the range of behavior of released la phytoplankton would have on the dissolv oxygen resources of the river, under critical flo temperature, and loading conditions. Simulatio for both stratified and nonstratified conditio were performed. The lack of density stratificati is predicted to result in greater stress on the syste and substantial contravention of river standar There are a number of limitations in this analys prime of which is the lack of unequivocal mod calibration. Further, the model framework may overly simplistic with respect to dimensionali and the omission of dispersive transport. Howeve more complex models have greater input requir ments. (Baker-IVI)

efforts to stop the disappearance of anadromous
h, crab, oyster, and plant life in the Chesapeake
y area, a study was undertaken which divided
e Bay into geographical units but kept in mind
e fact that each of these units works with the
hers in the total ecosystem picture. These units
cluded the tidal freshwaters at the heads of any
the dendritic tributaries that feed the bay, and
e turbidity-maximum area where circular cur-
nts raise a curtain of sediments and living things.
uman influence has been cited as the largest of the causes of the bay's ills. The ever increasing supply of nutrients in the estuary is possibly the major cause behind the thickening of the bay's waters. Scores of sewage plants along the Cheasapeake's tributaries are disgorging nitrogen and phosphorus, natural products of biological sewage treatment. Nitrogen comes in large part from the runoff of fertilizers. In the future, however, current findings indicate that atmospheric deposition of nitrogen especially as nitrate, may well overtake deposition from land runoff. (Baker-IVI)

MICROCOSM AND EXPERIMENTAL POND EVALUATION OF MICROBIAL COMMUNITY RESPONSE TO SYNTHETIC OIL CONTAMINATION IN FRESHWATER SEDIMENTS,
Tennessee Univ., Knoxville. Dept. of Microbiology.
G. S. Sayler, R. E. Perkins, T. W. Sherrill, B. K. Perkins, and M. C. Reid.
Applied and Environmental Microbiology, Vol. 46, No. 1, p 211-219, July, 1983. 3 Fig, 5 Tab, 17 Ref. OWRT grant 14-34-001-9096.

Descriptors: *Microorganisms, *Oil pollution, *Sediments, Water pollution effects, Synthetic oil, Hydrocarbons, Aromatic compounds, Ecosystems, Mineralization.

A multivariate approach was used to evaluate the significance of synthetic oil-induced perturbations in the functional activity of sediment microbial communities. Total viable cell densities, ATP-biomass, alkaline phosphates and dehydrogenase activity, and mineralization rates of glucose, protein, oleic acid, starch, naphthalene, and phenanthrene were monitored on a periodic basis in microcosms and experimental ponds for 11 months, both before and after exposure to synthetic oil. All variables contribute to significant discrimination between sediment microbial responses in control communities and communities exposed to a gradient of synthetic oil contamination. At high synthetic oil concentrations (4,000 ml/12 cu m), a transient reduction in sediment ATP concentrations and increased rates of oleic acid mineralization were demonstrated within 1 week of exposure. These transient effects were followed within 1 month by a signficant increase in rates of naphthalene and phenanthrene mineralization. After initial construction, both control and synthetic oil-exposed microbial communities demonstrated wide variability in community activity. All experimental microbial communities approached equilibrium and demonstrated good replication. However, synthetic oil perturbation was demonstrated by wide transient variability in community activity. This variability was primarily the result of the stimulation of polyaromatic hydrocarbon mineralization rates. In general, microcosms and pond communities demonstrated sufficient resiliency to recover from the effects of synthetic oil exposure within 3 months, although polyaromatic hydrocarbon mineralization rates remained significant elevated. PROBLEM OF CLASSIFICATION OF ACIDIFIED WATERCOURSES (ZUR PROBLEMATIK DER GUTEBEURTEILUNG VON SAUREN FLIESSGEWASSERN),
Gesamthochschule Kassel (Germany, F.R.). Fachbereich Biologie Chemie.
U. Matthias.
Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 3, p 107-110, 1983. 4 Fig, 1 Tab, 20 Ref.

Descriptors: *Acid streams, *Species composition, Kaufunger Wald, West Germany, Shrimp, Mayflies, Water pollution effects.

In the Kaufunger Wald Nature Park, situated east of Kassel, (Germany, F.R.) numerous small watercourses were investigated from the chemical/physical and faunistic viewpoints over a period of two years. It was discovered that a large number of the streams were acidified to varying degrees and had a much reduced biocoenosis in comparison with neutral watercourses. This species reduction had no influence on the classification, since all of the watercourses investigated were assigned to Quality Class I or I-II on the Hessian water classification map. In future water classifications, such acidification phenomena should be taken into account, since they result in a serious deterioration of the biocoenosis, as in the case of sewage input. In particular, the absence of acid-sensitive freshwater shrimps (Gammaridae) and mayflies (Ephemeroptera), which normally inhabit every non-polluted low-mountain brook, can provide evidence of possible acidification in weakly buffered waters with a low lime concentration. (Author's abstract)

INFLUENCE OF DISSOLVED OXYGEN LEVELS ON ACUTE TOXICITY OF PHENOLIC COMPOUNDS TO FRESH WATER TELECOST, NOTOPTERUS NOTOPTERUS (PALLAS),
Punjab Agricultural Univ., Ludhiana (India). Dept. of Zoology.
S. Gupta, R. C. Dalela, and P. K. Saxena.
Water, Air, and Soil Pollution, Vol. 19, p 223-228, 1983. 3 Tab, 15 Ref.

Descriptors: *Dissolved oxygen, *Toxicity, *Phenols, Organic compounds, Insecticides, Agricultural chemicals, 2,4-Dinitrophenol, Pentachlorophenol, Phenol, Fish, Notopterus.

Specimens of the fresh water fish Notopterus notopterus were exposed to phenol (P), 2,4-dinitrophenol (DNP), and pentachlorophenol (PCP) separately and in three combinations at three dissolved oxygen levels, 5, 6.5, or 7.8 mg/l for 96 hr in order to determine the influence of dissolved oxygen on the toxicity of phenolic compounds individually and in combination. A decrease in dissolved oxygen level from 6.5 mg/l increased the toxicity of P, DNP, PCP, and the three combinations by 88.0, 188.01, 219.0, and 123-610%, respectively. An increase in dissolved oxygen level from 6.5 to 7.8 mg/l decreased their toxicity by 31.0, 31.6, 22.5, and 23-55%, respectively. The increase in toxicity of these chemicals noted at low dissolved oxygen levels may be explained on the basis that at low dissolved oxygen levels fish must pass more water over the gills in order to obtain sufficient quantities of oxygen. As a result the fish absorb more toxicants via gills than they do at higher dissolved oxygen levels. Consistently, this produces lesions in the gills and also interferes with the normal gas exchange process. (Baker-IVI)

MACROBENTHOS OF LAKE NAINI TAL (U.P., INDIA) WITH PARTICULAR REFERENCE TO POLLUTION,
Kumaun Univ., Naini Tal (India). Dept. of Zoology.
P. K. Gupta, and M. C. Pant.
Water, Air, and Soil Pollution, Vol. 19, p 397-405, 1983. 6 Fig, 3 Tab, 16 Ref.

Descriptors: *Benthic environment, *Lakes, *Water pollution effects, Lake Naini Tal, India, Water depth, Benthos, Biological communities.

The important attributes of macrobenthic community structure such as species composition and number, population density, biomass, and dominance and diversity indices were measured at different depths and discussed in relation to pollution of Lake Naini Tal (India). The lake is fed by 22 seasonal and 2 perennial open drains carrying large amounts of domestic waste, urban runoff, and silt into the lake, which are main sources of pollution.

A total of 30 species were recorded from the entire lake. The total number of species, taxonomic groups, density, biomass and diversity index declined with depth up to 7 m; thereafter macrobenthos disappeared. Three different zones of pollution in the lake were distinguished: heavily polluted zone below 7 m, moderately polluted zone between 5 and 7 m depths, and pollution influenced zone from 0 to 5 m depths. As the major part of the lake had become afaunal, there is an urgent need to exercise control on the activities which tend to increase pollution. (Baker-IVI)

5D. Waste Treatment Processes

INTEGRATED WASTEWATER MANAGEMENT,
Asian Inst. of Tech., Bangkok (Thailand). Div. of Environmental Engineering.
B. R. Kansakar, and C. Polprasert.
Journal of Environmental Engineering, Vol. 109, No. 3, p 619-630, June, 1983. 2 Fig, 7 Tab, 15 Ref.

Descriptors: *Wastewater management, *Sludge management, Goal programming, Network design, Costs, Land use, Environmental effects, Water quality, Computer models, Interceptors, Sludge disposal, Routing.

A multiobjective goal programming method is proposed for use in analyzing problems involving a network flow structure which are commonly found in the wastewater and sludge management systems when cost functions are linear. The goals considered are the minimization of: (1) costs, (2) water quality impact, and (3) land use impact. The model also selects interceptor routes, treatment plants, transport routes and sludge disposal sites, along with flow directions through these facilities under optimal solutions. A hypothetical example problem dealing with regional wastewater management is analyzed to demonstrate the potential usefulness of the method. (Author's abstract)

ANAEROBIC BIOTECHNOLOGY FOR INDUSTRIAL WASTEWATER TREATMENT,
Drexel Univ., Philadelphia, PA. Environmental Studies Inst.
R. E. Speece.
Environmental Science and Technology, Vol. 17, No. 9, p 416A-427A, 1983. 4 Fig, 4 Tab, 97 Ref.

Descriptors: *Wastewater treatment, *Industrial wastewater, *Anaerobic conditions, Bacteria, Methanogens.

The majority of industrial wastewaters that appear to be good candidates for anaerobic treatment now require new phases of inquiry. The basic question centers around the rate at which the wastewater is degradable, and to what degree. The bioconversion of the organic feedstocks in industrial wastewaters to methane is accomplished by a consortium of bacteria comprised of chemoheterotrophic, nonmethanogenic bacteria and methanogenic bacteria. Methanogens are often considered the key class of microorganisms in anaerobic biotechnology. At least three cofactors are apparently unique to methanogens, and recently a newly discovered cofactor, 2-mercaptoethanesulfonic acid, has been found in all methanogens available in pure culture except Methanobacterium ruminantium, which requires it for growth. Since complex wastewaters containing organics have a continuous range of degradation rates, at low loading rates, the rate-controlling step may be acid formation, as is evidenced by low volatile acids concentrations. As the loading rate increases, the methanogenesis stage may gradually become the rate-controlling step, as evidenced by an accumulation of volatile acids. One problem which can be a serious hindrance to the commercialization anaerobic biotechnology lies in the lack of understanding of the trace nutrient requirements of methanogens. The number of substrates that have been proven amenable to anaerobic biotechnology is quite extensive. One major consideration inherent in anaerobic biotechnology is the relatively low synthesis ration of the methanogens. Special attention must be paid to ensure efficient retention of the biomass in the system. (Baker-IVI)

OPTIMIZING LARGE-SCALE WATER TREATMENT PLANTS FOR ASBESTOS-FIBER REMOVAL,
Southern California Metropolitan Water District, La Verne. Water Quality Branch.
M. J. McGuire, A. E. Bowers, and D. A. Bowers.
Journal of the American Water Works Association, Vol. 75, No. 7, p 364-370, July, 1983. 19 Fig, 4 Tab, 12 Ref.

Descriptors: *Water treatment, *Filtration, *Asbestos, Turbidity, Drinking water, Colorado River, California.

Standard and optimized treatment were alternated at five filtration plants in southern California that receive low to high concentrations of chrysotile asbestos fibers in their influents. The removals of asbestos fibers and turbidity by these plants are reported. Asbestos fiber concentrations in the five treatment plants influents were different because of the different sources of supply, the presence or absence of source-water reservoirs, and variations in the blends of the Colorado River water and the water in the state project. The ability of each plant to remove asbestos fibers was dependent on the asbestos concentration in the influent and the efficiencies of the individual treatment processes. In two cases (Weymouth and Diemer plants) a high percentage of removal of asbestos fibers did not result in levels as low as those at a plant that was less effective in particle removal. The 0.10 ntu goal for fiber effluent turbidity was not achieved on a consistent basis by all five treatment plants. One particular plant had trouble meeting the goal probably due to a problem with balancing flows and with a lack of continuous effluent turbidity monitoring equipment. Attainment of the 0.10-ntu level did not guarantee a low effluent asbestos concentration. In general, optimized treatment resulted in lower effluent asbestos concentrations than standard treatment. However, many of the effluent asbestos levels determined in this study were much higher than those reported in the literature. It appears that there is little hope of using 0.10 ntu as a surrogate level for asbestos fibers in treated drinking water. (Baker-IVI)

ENVIRONMENTAL STUDIES OF ENTERIC BACTERIA LONGEVITY IN MEMBRANE FILTER CHAMBERS,
National Water Research Inst., Burlington (Ontario). Analytical Methods Div.
B. J. Dutka, and K. K. Kwan.
Journal of the American Water Works Association, Vol. 75, No. 7, p 380-382, July, 1983. 2 Fig, 4 Tab, 9 Ref.

Descriptors: *Bacteria, *Seasonal variation, Wastewater treatment, Disinfection, Effluent, Water pollution sources, Escherichia coli, Klebsiella, Salmonella, Streptococcus, Serratia, Survival time, Public health.

Two studies were carried out over several seasons to ascertain the survival of pathogenic, indicator, and tracer bacteria in membrane filter chambers. The chambers were placed in a freshwater bay contaminated with industrial waste and domestic sewage and in a freshwater pond. Escherichia coli, Klebsiella pneumoniae, Salmonella thompson, Streptococcus faecalis, and Serratia marcescens were the bacteria used. The survival times for these bacteria were lengthy (>77 days) under either summer or winter conditions. Thus, the use of seasonal effluent disinfection might eventually result in bacterial contamination of downstream sediments and possibly of waters overlying these sediments. As a result of certain disturbances, these bacteria could be recycled throughout the water column and eventually into man or animals directly or indirectly through potable water supplies. Sewage must be disinfected throughout the year if receiving waters are to have any commercial or recreational value or are to be a safe source of potable water. (Moore-IVI)

ASSESSING THE SUITABILITY OF SOILS WITH MACROPORES FOR SUBSURFACE LIQUID WASTE DISPOSAL,
Stichting voor Bodemkartering, Wageningen (Netherlands).
J. Bouma, C. Belmans, L. W. Dekker, and W. J. M. Jeurissen.
Journal of Environmental Quality, Vol. 12, No. 3, p 305-311, July-September, 1983. 7 Fig, 28 Ref.

Descriptors: *Macropores, *Soil porosity, *Subsurface waste disposal, *Land disposal, Permeability coefficient, Simulation, Computer models, Ponding, Drainage, Soil breakthrough, Soil crust, Soil saturation.

The capacity of soils to accept and purify liquid waste can be manipulated by using different application regimes. The associated transient soil physical conditions, which govern purification processes, were measured experimentally in soil columns and in situ, and were predicted by simulation in three soils of which two had macropores. Measurements of pressure heads, outflow rates, and breakthrough curves were made following intermittent liquid applications of 2 cm/d. Rapid breakthrough and short-circuiting, which were observed in the soils with the macropores, could be reduced by adding a light crust. Predictions involved computer simulation of pressure heads during infiltration and redistribution, and of outflow rates in the columns. Good agreement was found between measured and calculated values, but only when the model for soils with macropores was modified to include a subprogram for macropore flow. Simulation required hydraulic conductivity (K) at and near saturation, which was obtained with a modified crust test procedure. Use of the simulation program allows the prediction of soil physical conditions for a range of application rates in terms of ponding times and drainage rates, which affect purification and clogging. Measurement of breakthrough curves yields travel times as a function of application rates. Optimal application rates can be estimated by considering these two types of data, as is illustrated with an example. This approach is preferred over the current procedure using a single hydraulic parameter. (Author's abstract)

Descriptors: *Biological wastewater treatment, *Anaerobic digestion, *Domestic waste, Temperature effects, Sludge, Wastewater treatment, Chemical oxygen demand.

Results obtained in a 120 liter 2 m high upflow anaerobic sludge blanket reactor with raw domestic sewage and using a granular sugar beet waste cultivated seed sludge, reveal the feasibility of this type of anaerobic treatment of domestic sewage. Under dry weather conditions 65-85% COD reduction can be achieved at temperatures in the range of 8-20 degrees C and at hydraulic loads as high as 2 cu m/cu m/day. In the case of heavy rainfall the COD-reduction drops to 50-70% and occasionally, at very low influent COD, even below 50%. The net methane production amounts to 7.1-7.3 cu m/population equivalent/year, and the excess sludge production ranges from 5.0-8.6 kg total solids/population equivalent/year. Anaerobic treatment of raw sewage not only appears to

LIBRARY U. OF L. URBANA-CHAMPAIGN

attractive proposition for tropic areas but
or moderate climatic areas. Generally the
bic treatment step should be followed by
dequate post-treatment in order to meet the
ions set for discharge of effluents into re-
waters. (Baker-IVI)

nnology is not a new field, having been used
water industry for a number of years in the
ses of activated sludge, biological filtration
aerobic digestion. These processes are cheap
fective and any radically different new proc-
would need to be shown to have major cost
rformance benefits. Biological wastewater
ent processes use naturally occurring proc-
nd employ natural selection of microorga-
arriving with the sewage to achieve the
end. The microorganisms of most impor-
is the bacterium although protozoa play a
ole in clarification of effluent and higher
sms are essential in the ecology of the perco-
filter. The biochemical reactions that the
a carry out include oxidation of organic
to carbon dioxide and water, oxidation of
nia to nitrate, oxidation of nitrite to nitrate,
ion of nitrates to nitrogen, conversion of
c matter to acetic acid, hydrogen and carbon
e, and conversion of acetic acid, hydrogen
rbon dioxide to methane. (Baker-IVI)

d solids, Methane, Sulfides, Ammonia.

oratory scale anaerobic filter packed with
tic high surface area trickling filter media
used to treat a low strength domestic
vater averaging 288 mg/l COD. The filter
perated for 60 days after reaching steady-
t 20, 25, 35 C at a loading rate of 0.02 lb
cu ft/day and 24 h hydraulic retention time.
effluent BOD 5 averaged 38 mg/l providing
rage removal rate of 79%, and effluent COD
ed 78 mg/l, corresponding to a 73% remov-
e. Removal efficiencies showed very little
vity to daily fluctuations in influent
vater quality. The filter performance at 25
C was not significantly different, but BOD
SS removal efficiency declined at 20 C. Gas
ction averaged 0.027 cu ft of gas per cu ft of
t wastewater, or 1.875 cu ft of gas per
of influent COD. Gas composition averaged
itrogen, 65% methane, and 5% carbon diox-
mmonia nitrogen and sulfides both increased
treatments. It is concluded that the anaero-
ter is a promising candidate for treatment for
rength wastewaters and that post treatment
lfides and ammonia may be necessary. (Au-

IARY TREATMENT OF MUNICIPAL
EWATER BY CYPRESS DOMES,
la Inst. of Tech., Melbourne. Dept. of Envi-
ental Sciences and Engineering.
Dierberg, and P. L. Brezonik.
Water Research, Vol. 17, No. 9, p 1027-1040, September, 1983. 9 Fig, 2 Tab, 27 Ref.

Descriptors: *Cypress domes, *Wastewater treatment, Municipal waste, Nitrogen, Phosphorus, Organic matter, Minerals, Dissolved oxygen, Tertiary wastewater treatment.

The feasibility of using cypress domes as an alternative to physical-chemical methods for tertiary treatment of sewage effluent was demonstrated over a 5 year period. Compared to effluent concentrations, rather small reductions, less than 33%, occurred in the concentrations of nitrogen, phosphorus, BOD, sodium, potassium, chloride, and fluoride in the surface waters of domes receiving treated sewage effluent. Larger reductions or about 50% occurred for calcium, magnesium and sulfate. The conventional treatment plant/oxidation pond itself was effective in reducing levels of BOD and total nitrate, but was ineffective in reducing levels of total phosphate and other minerals. The effectiveness of cypress domes in removing high percentages (greater than 90%) of organic matter, nutrients and minerals is more obvious when concentrations of these substances in the shallow watertable aquifer below the sewage-enriched domes are examined. Concentrations of these parameters in shallow wells in and around the sewage domes were at background levels throughout the study. High chloride values indicated that treated sewage was percolating into the shallow aquifer. Cypress domes and their associated sediments and soils thus can reduce the levels of major water quality parameters to levels comparable to those of conventional tertiary treatment processes. Sediments and vegetation continued to release inorganic ions to the standing water for more than 20 months after the cessation of sewage inputs. Parameters associated with organic matter and with the reducing environment of the sewage-enriched domes displayed a rapid return to background levels. (Baker-IVI)

NITRIFICATION BACK ON TRACK,
GRW Engineers, Lexington, KY.
D. L. Ralston.
Water Engineering and Management, Vol. 130, No. 7, p 29-30, July, 1983. 1 Fig.

Descriptors: *Wastewater treatment, *Nitrification, Sludge disposal, Activated sludge processes.

Continuous and conventional control practices proved to be sufficient to solve nitrification problems at an Ohio wastewater treatment plant. The Fairfield facility is a 6-mgd activated sludge plant with tertiary filtration and anaerobic digestion. Problems centered around the inability of the plant to meet NPDES requirements for ammonia nitrogen during the six summer months that the 2.5 mg/l effluent NH3-N limit is in effect. Problem areas identified included operator knowledge of the nitrification process and operational control techniques for solids handling; recycling of stream management; flow distribution to multi-basin unit processes; application of laboratory data to plant control, regulation of industrial discharges to prevent toxic influent slugs; and inclement weather sludge disposal. Correction of these problems lead to a satisfactory solution. (Baker-IVI)

GROWING A NEW TREATMENT PLANT FROM OLD ROOTS,
Camp, Dresser and McKee, Inc., Atlanta, GA.
C. S. Wilder, and G. Johnson.
Water Engineering and Management, Vol. 130, No. 10, p 28-31, September, 1983. 8 Fig.

Descriptors: *Water treatment facilities, *Water pollution control, Rivers, Georgia, Atlanta, South River, Jackson Lake, South River Basin, River basins.

The upgrading and expansion of the South River Wastewater Treatment Facility is a project which has practically cut a very old plant back to its root to allow a modern facility to arise in efforts to clean up the three rivers that flow through Atlanta. Wastewater discharges from plants in Atlanta and DeKalb County, and the city's three major combined sewer overflows are severely polluting the South River. The South River plant was originally designed in 1936 for an average daily flow of 6 mgd with primary settling, low-rate trickling filters, final settling and effluent chlorination. The multiple-project designed for the Three Rivers area will, when completed, comprise a 37 mgd South River Wastewater Treatment Plant which nitrifies the Intrenchment Creek Plant effluent and provides complete treatment for the previous influent to the Flint River Plant. Modifications are called for to the existing 20 mgd Intrenchment Creek Plant including effluent pumping facilities for discharge to the South River Plant for nitrification. The existing 6-mgd Flint River Plant will be replaced by a pump station for discharging raw wastewater to the South River Plant for treatment. A diversion system will provide a gravity sewer connection to transfer South River Plant effluent to the Chattahoochee River, and two combined sewer overflow facilities will be established with partial treatment to reduce the pollution load in receiving waters in the Three Rivers Program area during certain rainfall conditions. EXPERTS DISCUSS PRIVATE SECTOR INFILTRATION/INFLOW.
Water Engineering and Management, Vol. 130, No. 10, p 32-42, September, 1983.

Descriptors: *Infiltration, *Water treatment facilities, Wastewater treatment, Management, Decision making.

Most of the national emphasis on infiltration and inflow (I and I) source rehabilitation has been associated with public sector sewers. While this is certainly important, private sector I and I can also be significant. I and I in sanitary sewer systems can affect treatment plant compliance, cause sewer backups and overflows, require excessive expenditures for oversized treatment plants, and bring about no-growth conditions. A panel of four experts has agreed that identification and correction of private sector I and I can be implemented as part of a total sewer rehabilitation program. Special procedures may be needed, consisting primarily of public education and enforcement of municipal utility ordinances. Significant I and I flow reduction may not be possible if the private sector is not addressed. Political and legal issues may have an effect on the ultimate success of the private sector program in various communities. Clarification of existing regulations is required in some places. Managers in charge of other sewer rehabilitation programs across the country should consider the potential impact of all I and I sources on the sewer system - public and private. (Baker-IVI)

TIGHT EFFLUENT SPECS MET WITH DIGITAL CONTROL,
Upper Occoquan Sewage Authority, Centreville, VA.
M. H. Robbins, Jr.
Water Engineering and Management, Vol. 130, No. 11, p 30-36, October, 1983. 2 Fig, 1 Tab.

Descriptors: *Water treatment facilities, *Computers, Regulations, Standards, Wastewater treatment, Occoquan Policy, Virginia.

The Occoquan Policy formulated in Virginia in 1971 called for the construction of an advanced wastewater treatment plant, controlled largely by a computer-aided system. To ensure reliable performance, the facilities incorporate many failsafe features. Both the plant and the collection system are designed so that a single failure of a mechanical or electrical component will not interrupt operations essential in meeting the effluent requirements. The instrumentation and control system has four levels of control: manual, analog hardware, direct digital, and direct digital with analog backup. The instrumentation and control system

WASTE WATER COMBUSTION IN A CONFINED SWIRL FLAME,
Duisburg Univ. (Germany, F.R.).
P. Roth, and R. Shamekhi.
Chemical Engineering Science, Vol. 38, No. 7, p 1101-1106, 1983. 8 Fig, 17 Ref.

Descriptors: *Wastewater treatment, *Nitrogen compounds, *Combustion, Industrial wastewater, Thermochemical conversion, Ammonia, Aminoethanol, Caprolactam, Evaporation, Nitrogen oxides, Water reuse.

In some industrial production processes water with dissolved or dispersed organic or inorganic chemical compounds is originated which cannot be biologically treated. One possible way of recycling is high temperature thermochemical conversion in flames. Particular problems are caused by waste water which contains nitrogen compounds. Water with the dissolved N-compounds ammonia, aminoethanol and epsilon-caprolactam (NH3, C2H7NO and C6H11NO) was sprayed into a confined swirl flame operating under various conditions. The model waste water and the atomizing fluid influence the visible flame structure. The rates of mixing and evaporation in the recirculation zone of the combustor flow are high enough to make the droplets quickly vanish. The water dissolved N compounds are assumed to be fully present in the gas phase. The NO yield can be predicted by using Fenimore's empirical correlation function derived from measurements on fuel-N conversion of premixed flames. This fundamental relationship seems to be applicable for very complex combustion situations and in an engineering sense can be used to predict the N conversion factor. (Moore-IVI)

WETLANDS FOR WASTEWATER TREATMENT,
J. Benforado.
EPA Journal, No. 2, p 14-15, October, 1983. 2 Fig.

Descriptors: *Wetlands, *Wastewater treatment, Water plants, Walt Disney World, Florida, San Diego, California.

An aquaculture project funded by the city of San Diego is part of a pilot test advanced treatment facility that treats raw sewage to standards higher than those used for tap water in many cities. Lagoons filled with water hyacinths are used to clean the water. Similar installations ar%;Y at NASA labs at Bay St. Louis, Miss., and at Walt Disney World, Orlando, Florida. In the latter location waste discharge is first given a high degree of secondary treatment and is then treated by one of four different methods. The major portion of effluent is discharged to a cypress swamp, another portion is used for spray irrigation, and overflow from ponds is sent through a cattail marsh. A water hyacinth system has also been constructed for experimental use. In addition to providing waste treatment, managed wetlands can also contribute many other benefits including offering sanctuary to migrating birds. Wetlands purify wastewater through physical entrapment of pollutants in the surface soils and organic litter. (Baker-IVI)

EFFECT OF MEMBRANE MATERIALS AND AVERAGE PORE SIZES ON REVERSE OSMOSIS SEPARATION OF DYES,
National Research Council of Canada, Ottawa (Ontario). Div. of Chemistry.
L. Tinghui, T. Matsuura, and S. Sourirajan.
Industrial and Engineering Chemistry, Product Research and Development, Vol. 22, No. 1, p 77-85, 1983. 3 Fig, 7 Tab, 32 Ref.

Descriptors: *Reverse osmosis, *Dyes, *Membrane processes, Wastewater treatment, Dye industry wastes, Liquid chromatography.

Reverse osmosis separations of 13 dyes were conducted by using cellulose acetate and aromatic polyamidohydrazide membranes of various average pore sized at operating pressures in the range 689 to 1723 kPag. High performance liquid chromatography (HPLC) experiments were also performed with respect to all dyes studied using chromatography columns filled with powders of membrane polymer materials. Interfacial force constants A, B, and D, which are associated with the electrostatic force, van der Waals force, and steric hindrance, respectively, were generated by applying the transport equations to the data from reverse osmosis and HPLC experiments. The interactive forces depend on the chemical structure of the dye molecule and the membrane material, when solvent is fixed as water. They are primarily governed by the net electric charge, polar and nonpolar organic functional groups of dye molecules, and by the acidity-basicity nature of the membrane materials. The force constants enable the prediction of the dye solute separation for a given average pore radius of the membrane. This provides a basis for the choice of membrane materials for use in reverse osmosis applications involving separation of dyes in aqueous solutions, such as the treatment of dye-laden wastewaters. WASTEWATER TREATMENT - AN AWARD-WINNING SYSTEM,
Amoco Chemicals Corp., Joliet, IL.
G. P. Chodil.
Hydrocarbon Processing, Vol. 62, No. 10, p 61-64, October, 1983. 5 Fig, 1 Tab.

Descriptors: *Wastewater treatment, *Industrial wastes, Activated sludge process, Aeration basins, Filtration, Lagoons, Joliet, Illinois.

The Joliet, Illinois facility's wastewater treatment facility is an activated sludge plant consisting of primary basins for equalization of feed surges; aeration basins for biological oxidation of dissolved organics; clarifiers for solids/liquids separation; and polishing facilites including dissolved air flotation, ponds and filters for final treatment of the effluent before discharge to the Des Plaines River. The Amoco plant itself has a production capacity of 500 million pounds per year of raw materials for polyester fiber and film and polystyrene industries. The organic acid content of the wastewaters from the plant results in a total organic carbon concentration of 3,000-4,000 mg/l and a pH of about 4. About 0.5 MMgal per day of these high strength organic acid wastewaters are treated in an activated sludge process before final discharge. (Baker-IVI)

IMPROVE PLANT WATER QUALITY,
Du Pont de Nemours (E.I.) and Co., Beaumont, TX.
W. W. Carden.
Hydrocarbon Processing, Vol. 62, No. 10, p 75-77, October, 1983. 3 Fig, 1 Tab, 2 Ref.

Descriptors: *Water treatment, *Industrial water, *Polyelectrolytes, Coagulation, Clarifiers, Sedimentation, Turbines, Fouling, Beaumont, Texas.

Producing high quality water for various in plant uses is of prime concern as long as the processes used are reliable and cost effective. Synthetic organic polyelectrolytes have been used effectively instead of the inorganic coagulants by DuPont's Beaumont (Texas) plant. The plant had used alum/activated silica as coagulant materials for many years. The switch to polyelectrolyte coagulant materials for influent water clarification enabled the plant to meet its more stringent water quality criteria and eliminate the adverse effect of alum treatment. Simple sedimentation has been enhanced through employment of the principles of stabilizing suspensions. Clarification of water is accomplished by two basic mechanisms: electrokinetic coagulation in which the electrostatic charge is neutralized, and orthokinetic coagulation in which the high molecular weight molecules bridge the microflocs into larger, faster settling particles. An adjustment has also been made in the turbine which has reduced significantly the tende cy for solids buildup. The elimination of alu fouling has enables the manufacturing facility avoid production curtailment formerly caused heat exchanger fouling and to eliminate one fiv day annual outage for heat exchanger cleanin (Baker-IVI)

ANAEROBIC WASTEWATER TREATMEN SYSTEM HANDLES HIGH-STRENGTH IN DUSTRIAL WASTE,
Celanese Chemical Co., Bishop, TX. Process Engineering Dept.
L. M. Harvey, and J. C. Rubiano.
Paper Trade Journal, Vol. 167, No. 6, p 28-3 March 30, 1983. 1 Fig, 2 Tab.

Descriptors: *Anaerobic digestion, *Wastewate treatment, Industrial wastewater, Hydrogen io concentration, Heavy metals, Chemical oxyge demand.

The Celrobic Wastewater Treatment System i operation at the Celanese plant at Bishop, Texa was designed to meet projected plant wastewate treatment needs through 1989. The system ha demonstrated a high degree of flexibility for treat ing liquid effluents with widely varying pH o concentrations of COD or heavy metals. The addi tion of the anaerobic reactor upstream of the plant's existing activated sludge system has made possible the treatment of process effluent streams which could not be treated in conventional aerobic systems. The addition of the Celrobic Wastewater Treatment System has increased not only the capacity but also the reliability of the wastewater treatment system at the plant. Improved reliability and economic advantages of methane gas credits and reduced sludge production have proven the retrofit of the Celrobic System to the existing activated sludge system to be the superior alternative for expanding the wastewater treatment facilities at the Bishop Plant. PHOSPHORUS AND BACTERIA ELIMINATION IN A SEWAGE TREATMENT PLANT WITH A FOURTH PURIFICATION STAGE (WEITESTGEHENDE PHOSPHOR- UND BAKTERIENENTFERNUNG IN EINER KLARANLAGE MIT IV. REINIGUNGSSTUFE),
Zurich Univ., Kilchberg (Swizerland). Hydrobiological-Limnological Station.
R. Mosimann, and F. Schanz.
Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 5, p 161-167, 1983. 7 Fig, 3 Tab, 17 Ref.

Descriptors: *Tertiary wastewater treatment, *Phosphorus removal, *Coliforms, *Enteric bacteria, Uster, Switzerland, Storm runoff, Rainfall, Wastewater treatment, Sludge basins.

The degree to which phosphorus is eliminated in a sewage treatment plant with a fourth purification stage and the the extent of retention of fecal bacteria (coliform bacteria and enterococci) by the sewage works are considered. The sewage treatment plant chosen for this study is situated in Uster (canton of Zurich, Switzerland). In dry weather, the plant was able to eliminate 96% of total phosphorus; however only 21% of the measured outflow values lay at or below the prescribed value of 0.2 mg total P/l. During a period of rain, even strongly increased amounts of solid waste, such as are swept from roofs, streets and drains, are retained in the fourth purification stage. This contrasts with sewage treatment plants having only two or three purification stages, where considerable amounts of sludge are deposited in the receiving watercourse. As a result of the increased rates of flow and the corresponding short residence time in the sludge basins, a strong increase is observed in the amount of phosphorus in the outflow during the period of rain, in comparison to the conditions existing during dry periods. The fecal bacteria were found to be 92% retained by the fourth stage alone. The final concentration of fecal bacteria in the purified wastewater amounts to only about

of that in the raw sewage entering the plant.

permeate flux from a spiral-wrap ultrafiltra-
membrane is a complex function of inlet pres-
reject flowrate, polymer concentration and
e of membrane fouling. A mathematical
el is presented that describes the permeate flux
e and after the onset of gel-polarization. The
f the model in evaluating the effects of mem-
fouling and cleaning strategies on plant per-
ance is discussed with reference to polyvinyl
ol textile size recovery. The two main effects
h determine the permeate flux of a clean mem-
brane are the transmembrane driving force and the formation of a polymer gel-layer adjacent to the membrane. For very dilute solutions the permeate flux increases with the average transmembrane pressure, which is at a maximum when the reject valve is closed and decreases as the reject flowrate increases. For solutions which form gel-layers, the permeate flux is limited because the formation of a gel-layer implies that the process becomes diffusion controlled. An increase in the reject flowrate decreases the thickness of the gel-layer resulting in an increase in flux. The model assumes that for any particular position along a membrane element, conditions will either be those of gel-polarization or such that the eddies in the reject flow will be adequate to scour the surface. From a network analysis, the optimal configuration of membrane elements shows that significant savings in membrane area and pumping costs are achievable. (Baker-IVI)

MEMBRANE FILTRATION FOR THE REUSE OF CITY WASTE WATER,
Danske Sukkerfabrikker, Nakskov. Reverse Osmosis Div.
O. J. Olsen, and U. H. Haagensen.
Desalination, Vol. 47, p 257-265, 1983. 6 Fig, 3 Tab, 5 Ref.

Descriptors: *Desalination, *Filtration, *Membranes, Membrane processes, Ultrafiltration, Municipal wastes, Wastewater treatment, Reverse osmosis, Wastewater renovation.

Membrane filtration represents a feasible alternative for recovery and upgrading of municipal wastewater. A secondary municipal effluent from a plant with a combined mechanical-aerated pond treatment was treated by ultrafiltration. The ultrafiltration performed satisfactorily over a testing period of two and a half months. An economic evaluation of the process shows that the operational costs and the capital costs amount to about 0.5 US dollars per cubic meter of filtrate. Reverse osmosis operation showed that a large improvement in capacity could be obtained by pretreatment of the effluent by ultrafiltration compared to untreated effluent. However, it is obvious that ultrafiltration as a pretreatment method generally does not solve the fouling problem found in the reverse osmosis operation. It is anticipated, nevertheless, that wastewater from plants with higher cleaning efficiency will lead to improved reverse osmosis operations. The characterization of secondary effluent is complex and the performance of reverse osmosis will be to a large extent based on a number of unknown factors in connection with chemical composition of the water and efficiency of the sewage treatment plant. APPLICATION OF MEMBRANE SEPARATION PROCESSES TO THE TREATMENT OF INDUSTRIAL EFFLUENTS FOR WATER REUSE,
Natal Univ., Durban (South Africa). Dept. of Chemical Engineering.
G. R. Groves.
Desalination, Vol. 47, p 277-284, 1983. 1 Fig, 3 Tab, 4 Ref.

Descriptors: *Desalination, *Wastewater treatment, *Membrane processes, Reverse osmosis, Water quality control, Waste disposal, Water reuse, Wastewater renovation, Industrial wastewater.

The discharge of industrial effluents into the water environment is being made more difficult through environment pollution regulations passed to preserve water quality. The applicability and scope of membrane technology for treatment of industrial effluents is gaining ground. The membrane separation techniques, and in particular reverse osmosis, have tremendous potential due to their ability to remove organic and/or inorganic compounds in a one-step process at a reasonable cost. The main problem is the susceptibility to fouling by insoluble salts and certain organic compounds. The major considerations for the application of membrane technology to the treatment of industrial effluents are pretreatment, membrane type, module type and configuration, cleaning requirements, rejection performance and economics. When considering the disposal of the final concentrates from membrane treatment plants, reverse osmosis plants may be considered as concentrating devices for the production of concentrates of total solids in the range of 60-100 g/l, depending on the osmotic backpressure and maximum module operating pressure. For most treatment of industrial effluents, the membrane flux rates will be fairly low and hence reverse osmosis plants cannot be designed on an once-through basis. This is overcome by interstage recycling on series-taper plants or by using batch concentration. Cost effectiveness is improved with increasing membrane production volumes and enhanced reliability of membrane treatment plants. (Baker-IVI)

REVERSE OSMOSIS TREATMENT AND REUSE OF TEXTILE DYEHOUSE EFFLUENTS,
Natal Univ., Durban (South Africa). Dept. of Chemical Engineering.
K. Treffrey-Goatle, C. A. Buckley, and G. R. Groves.
Desalination, Vol. 47, p 313-320, 1983. 2 Fig, 2 Tab, 7 Ref.

Descriptors: *Wastewater removation, *Dye industry wastes, *Reverse osmosis, Membrane processes, Filtration, Water reuse, Color.

A 30 cubic meter/d pilot plant consisting of screening, alum coagulation, microfiltration and reverse osmosis was operated for 2 years on cotton/nylon/polyester dyehouse effluents. The reverse osmosis modules used were the brackish and seawater UOP PA300 type. The pilot plant operated at water recoveries of 85-95% and temperatures of 30-45 degrees C. The microfiltration unit was used to remove suspended solid and colloidal dyestuffs from the effluent prior to the spiral-wrap membranes. The average permeate flux was 15 l/sq m/hour. The average permeate quality was 60 mg/l of total dissolved solids, 15 mg/l of sodium, 11 mg/l of TOC and 21 ADMI color units. The product water was reused routinely for production dyeing. While fairly severe membrane fouling occurs, it has been controlled through regular cleaning of the membranes. (Baker-IVI)

MAKE-UP WATER TREATMENT AT THERMAL POWER PLANTS AND MULTIPLE WASTE WATER RE-USE,
O. I. Martynova, A. I. Abramov, A. S. Sedlov, L. G. Vasina, and I. P. Iljina.
Desalination, Vol. 47, p 321-325, 1983. 2 Fig, 1 Tab, 3 Ref.

Descriptors: *Demineralization, *Powerplants, *Wastewater treatment, Water reuse, Ion-exchange, Evaporation, Make-up water, USSR.

Currently, demineralization of make-up water for the compensation of steam and condensate losses at thermal power stations is carried out mainly by ion exchange. Substantial ecological advantages can be achieved through the use of thermal water treatment with evaporators. At some thermal powerplants in the USSR boiling type evaporators are fed with sodium-cation exchange softened water to get demineralized make-up water. Thermal demineralization using sodium cationized water makes it theoretically possible to minimize wastewater salt content, if it is used repeatedly for sodium cationite filters regeneration. TREATMENT OF PULP/PAPER BLEACH EFFLUENT BY REVERSE OSMOSIS,
Sappi Ltd., Enstra (South Africa). Dept. of Research and Development.
M. J. Simpson, and G. R. Groves.
Desalination, Vol. 47, p 327-333, 1983. 4 Fig, 5 Tab, 6 Ref.

Descriptors: *Reverse osmosis, *Bleaching wastes, Pulp wastes, Industrial waste, Wastewater treatment, Bleaching wastes, Pulp and paper industry, Membrane processes.

The reverse osmosis treatment of bleach effluents from pulp and paper manufacturing is becoming of increasing importance because of environmental considerations. Investigations on the treatment of bleach effluent with three thin-film composite reverse osmosis membranes are presented. Membrane fouling was significant and was only partially controlled by the manufacturers recommended cleaning procedures. The three membranes tested were: Filmtech brackish water FT30 in a 100 mm diameter spiral-wrap module (type BW30-40-14); UOP brackish water PA300 in a 100 mm diameter spiral-wrap module (type 4600PA); and DDS brackish water HR95 in flat-sheet form. Membrane rejections were above 90% for both inorganic and organic components, for a total solids range of 5-30 g/l. While thin-film composite membranes have good rejections of the organic components of bleach effluents, the membrane fluxes are unacceptably low for the direct treatment of the effluent. (Baker-IVI)

STUDIES ON THE APPLICATION OF RO IN TREATMENT OF RAYON PLANT EFFLUENT,
Indian Inst. of Tech., Bombay. Dept. of Chemical Engineering.
S. Basu, and S. Moulik.
Desalination, Vol. 47, p 335-342, 1983. 5 Fig, 13 Ref.

Descriptors: *Reverse osmosis, *Textiles, Rayon, Industrial wastes, Water reuse, Turbulent flow, Laminar flow, Wastewater treatment, Wastewater renovation, Water pollution control.

Reverse osmosis is evaluated for the treatment of spinning bath and washing effluent stream for water/chemicals reclamation, along with pollution abatement. Initial membrane evaluation was carried out in a reverse osmosis test loop having 1 mm feed channel height and 0.60 sq cm flow cross sectional area with cellulose diacetate membrane, and thin film amide composite membrane (PA-300). Under varying flow rates concentration polarization modulus was pronounced at low concentrations of sodium sulfate solution (2%), while it was lower at higher concentrations (12%). At higher flow rates, however, polarization modulus was more or less constant, varying between 1.075 to 1.10, depending on feed concentrations and type of membrane used. Mass transfer coefficients calculated from experimental results showed good agreement with predicted data. (Baker-IVI)

STUDY OF EMULSIFIED LIQUID MEMBRANE TREATMENT OF PHENOLIC WASTE WATER,
Y. C. Chang, and S. P. Li.
Desalination, Vol. 47, p 351-361, 1983. 10 Fig, 2 Tab, 7 Ref.

Descriptors: *Phenols, *Wastewater treatment, *Membrane processes, Liquid membrane extraction, Chemical recovery.

The emulsified liquid membrane extraction technique is a new and effective method for separation of mixtures with applications in the nuclear industry, hydrometallurgy and wastewater treatment. The emulsified liquid membrane is made by forming an emulsion of two immiscible phases and then dispersing the emulsion in a third phase (i.e. continuous phase). Phenolic wastewater was treated containing 300-950 ppm of phenol with aqueous NaOH solution in an oil type liquid membrane. The treatments were performed in a batch permeater and a continuous counter-current extraction column respectively. In a batch operation, under suitable conditions, 98% of the phenol could be removed from phenolic wastewater and the rate of breakage of the emulsion drops was less than 1% per hour. The overall diffusivities of phenol through the liquid membrane are constant. A continuous counter-current liquid membrane extraction column (6.2 cm diameter, 120 cm long) was installed and its efficiency examined. The height of the theoretical stage of the liquid membrane extraction column was about 160-190 cm. If extraction of phenol from a waste water containing 500 ppm phenol was performed in a column with efficiency of one theoretical stage, more than 99% of phenol might be removed by such a liquid membrane process. SEWAGE SLUDGE FOR CULTIVATING FRESHWATER ALGAE AND THE FATE OF HEAVY METALS AT HIGHER TROPHIC ORGANISMS; I. DIFFERENT METHODS OF EXTRACTING SEWAGE SLUDGE ON THE PROPERTIES OF SLUDGE EXTRACTS,
Hong Kong Polytechnic, Kowloon. Dept. of Applied Science.
F. Y. Tam, and M. H. Wong.
Archiv fur Hydrobiologie, Vol. 96, No. 4, p 475-485, April, 1983. 2 Fig, 1 Tab, 38 Ref.

Descriptors: *Sludge disposal, *Heavy metals, *Algal growth, Aquaculture, Recycling, Waste recovery.

The main aim of this project is to (1) recycle sewage sludge into an unconventional protein material through the cultivation of unicellular algae in water extracts of sewage sludge and (2) study the fate of heavy metals at higher trophic organisms by using the waste-grown algae in rearing other aquatic organisms. In the first part of the project, different methods were employed to extract sewage sludge. Autoclaving was the most effective method in recovering essential nutrients as well as heavy metals from sewage sludge, following by shaking; whereas homogenizing was the least effective. The pH value of the extractant was the main factor in determining the content of heavy metals in sludge extracts. The two extreme pH (2 and 12) yielded extracts with higher essential nutrients. The amount of heavy metals released was negatively correlated to the extractant pH. (Author's abstract)

WASTE CONCENTRATION VS EVAPORATION PONDS FOR REVERSE OSMOSIS REJECT WATER - A CASE STUDY,
Water Services of America, Inc., Milwaukee, WI.
G. F. Leitner.
Desalination, Vol. 44, p 31-38, 1983. 2 Fig, 4 Tab, 4 Ref.

Descriptors: *Reverse osmosis, *Evaporation ponds, *Brine disposal, Desalination, Water resources development.

With the almost universal acceptance of the reverse osmosis process for desalination of brackish waters and its resulting widespread use throughout the world, it becomes increasingly important to seek out ways for further cycle improvement. One area for improvement has been the avoidance of possible contamination of groundwaters through lining reject ponds with synthetic rubber or similar material to prevent seepage into the soil. New developments in the distillation field have resulted in reduced energy requirements for concentrating distillation units. These developments make it practical to consider using vapor compression distillation in combination with reverse osmosis plan inland locations where lined ponds are re due to investment limitations. A case study water project is offered to determine if f concentration of the reject water by distil would be a cost effective solution. (Baker W84-02022

REACTION RATES OF POLYNUCLEAR A MATIC HYDROCARBONS WITH OZON WATER,
Institut Rudjer Boskovic, Zagreb (Yugoslavia)
V. Butkovic, L. Klasinc, M. Orhanovic, J. Tu and H. Gusten.
Environmental Science and Technology, Vo No. 9, p 546-548, 1983. 2 Fig, 1 Tab, 17

Descriptors: *Polynuclear aromatic hydrocarb *Ozone, *Rate constants, Ozonation, Py Phenanthrene, Benzo(a)pyrene, Disinfection, inactivation, Water treatment.

The rate constants for the reaction of pyr phenanthrene, and benzo(a)pyrene with ozon water were determined by means of stopped-spectrometry. The second-order rate const amount to about 40,000, 15,000, and 6,000 cu mol/s, respectively, over the pH range 1-7. corresponding half-lives in presence of 0.000 ozone at pH 7 are less than a second, i.e., they 10,000 times shorter than the values for pyrene benzo(a)pyrene that are dissipated widely in literature. Since ozonation used for the bact disinfection and viral inactivation of drin water usually affords ozone contact times of 4 one can expect that within this time and with ozone dosage of about 1 mg/L, all of the poly clear aromatic hydrocarbons will be oxidized c pletely. The rate constants may also be used for prediction of half-lives of polynuclear arom hydrocarbons in the lower atmosphere. (Moo IVI)

scriptors: *Groundwater pollution, *Tetrachlor-hylene, *Water pollution sources, *Water pollu- control, Test wells, Purge wells, Water distri-ion, Chlorinated hydrocarbons, Kalamazoo, chigan.

npling of the Kalamazoo, Michigan, water ply showed 10 micrograms/L of tetrachlor-hylene from an unknown source in a portion of city's water distribution system and in one of city's well fields. The contaminated well was nediately removed from service and pumped to te. A land use study, a theoretical piezometric face, and sequential well drilling techniques fa-ated locating the source and determining the ent of the contamination. An abandoned dry aning business was found to be the source of the tamination. Using the two most contaminated duction wells as purge wells has thus far been effective means of protecting the remainder of well field from further increases in tetrachlor-hylene contamination. To reduce the likelihood any other contamination reaching the central l field undetected, the utility has proposed that mplete well monitoring system be built around central well field to serve as an early warning tem. scriptors: *Treatability, *Water treatment, roundwater pollution, Heavy metals, Organic npounds, Waste dumps, Aquifer restoration, emical precipitation, Steam stripping, Activated bon, Adsorption, Biological treatment, Physico-emical treatment.

e contamination of groundwater by toxic organ-chemicals is becoming a widespread concern in United States. The once abundant supply of contaminated groundwater has diminished to the gree that treatment of contaminated groundwat- is being required for direct use and for aquifer toration or reclamation. Removal of organic emicals requires treatability studies to determine proper treatment processes and the proper sign of these processes. Treatability studies show t the volatile organics, extractable organics, and rganics (heavy metals) of concern in the con-minated groundwater near a hazardous waste mp site can be treated successfully by two alter-ive processes. One process consists of chemical ecipitation to remove metals, steam stripping, d activated carbon adsorption. The alternative ocess consists of combined physical-chemical d biological treatment. escriptors: *Hydrogen sulfide, *Groundwater llution, *Water treatment, Sulfide removal, rinking water, Ferrous sulfate, Peroxides, Per-anganates, Ferrates, Cost analysis.

ne removal of hydrogen sulfide from groundwat- supplies was investigated by using various cata-sts and oxidants in bench-scale jar tests that mulated assumed actual conditions in a water eatment plant. Variations in aeration rate, chemi-l dosage, recycled solids, pH, and detention time ere also examined. A ferrous sulfate dosage of 9 g/L reduced sulfide concentrations to 0.05 mg/ largely owing to the catalytic effect of Fe(II). eroxide, permanganate, and ferrate also lowered e sulfide concentrations, with more rapid kinetics than Fe(II). An economic analysis showed that Fe(II) is a cost-effective alternative for sulfide removal. The other oxidants may also prove economical under certain conditions. (Author's abstract)

DETERIORATION OF WATER QUALITY IN LARGE DISTRIBUTION RESERVOIRS (OPEN RESERVOIRS).
Journal of the American Water Works Association, Vol. 75, No. 6, June, 1983. 4 Tab, 40 Ref.

Descriptors: *Water quality, *Reservoirs, Water storage, Seattle, Washington, Hackensack, New Jersey, Southern California, Monitoring, Bacteria, Phytoplankton, Turbidity, Algal growth, Temperature effects, Seasonal variations.

The quality of water in open, filtered-water reservoirs of three distribution systems was monitored in order to ascertain the degree to which water quality deteriorates during storage in the reservoirs. Data are presented from monitoring programs conducted in southern California, Seattle, Washington and Hackensack, New Jersey. In California the water quality parameters met the 1977 standards at all times and all locations. Turbidity occasionally increased to levels exceeding 1 tu. Trihalomethane levels varied but were frequently greater than the 100 microgram/liter standard established by the USEPA for drinking water. Substantial bacterial populations existed in the reservoirs. Algal populations grew to nuisance proportions several times during the study. Chemical airborne inputs do not appear to influence reservoir dynamics significantly, but bacteria may enter the reservoirs through airborne transport. Significant detrimental changes were noted in water quality after reservoir storage. While many significant interrelationships were found between the various parameters that were measured, no key parameters were found whose limitation might inhibit deterioration of water quality in the reservoirs. The difference between evaporation loss and precipitation gain in the reservoirs was relatively small. No significant differences in water quality were noted between various sites in the reservoirs. Seattle studies indicated no problems with phytoplankton but bacterial populations did contribute to water quality degradation in varying degrees, and some of the reservoirs clearly demonstrated an inadequate storage capacity. New Jersey studies showed turbidity levels increasing during warm months with algal populations being the main influence. Bacterial populations increased slightly with postchlorination maintaining a quality equivalent to that of water leaving the treatment plant. Nutrients such as nitrite, nitrate, phosphate and dissolved oxygen were not significantly affected by the open reservoirs. Trihalomethane levels varied as a function of the surface water supply. (Baker-IVI)

WASTEWATER REUSE: A RESOURCE OR A NUISANCE,
American Water Works Association Research Foundation, Denver, CO.
J. G. DeBoer.
Journal of the American Water Works Association, Vol. 75, No. 7, p 348-356, July, 1983. 4 Tab, 19 Ref.

Descriptors: *Water reuse, *Potable water, *Water treatment, Water quality, Water conservation, Wastewater renovation, Groundwater recharge, Reclaimed water.

As demand for good quality water increases, some areas in the United States find that traditional finite sources cannot meet all needs. Although many utilities draw potable supplies from water that has previously been used upstream, the direct reuse of treated water for potable supplies is limited by unknowns concerning health effects and by costs. Planned reuse options, however, are feasible water conservation techniques, especially for industrial and agricultural uses. Reclaimed wastewater can also be used to recharge groundwater, thereby augmenting potable supplies. (Author's abstract)

COLIFORM OCCURRENCE AND CHLORINE RESIDUAL IN SMALL WATER DISTRIBUTION SYSTEMS,
Drexel Univ., Philadelphia, PA. Dept. of Biological Sciences.
M. A. Goshko, W. O. Pipes, and R. R. Christian.
Journal of the American Water Works Association, Vol. 75, No. 7, p 371-374, July, 1983. 1 Fig, 5 Tab, 15 Ref. EPA grant R-805637.

Descriptors: *Residual chlorine, *Coliforms, *Water distribution systems, Escherichia coli, Enterobacter, Klebsiella, Chlorination, Disinfection.

Samples were collected from seven small (0.09-11 ML/d) municipal water systems. Statistical analyses showed that for systems in which the free chlorine residuals vary considerably, there is no association between coliform density and a free chlorine residual of <0.2 mg/L. Enterobacter cloacae and Enterobacter agglomerans were found in samples with a free chlorine residual >0.2 mg/L, whereas Escherichia coll was found only in samples without a free chlorine residual. Some other coliforms species were found at the higher chlorine residuals; however, at all but one site they were found in association with Enterobacter. Klebsiella pneumoniae was found at one site with a free residual chlorine of 0.45 mg/l and with no Enterobacter present. If the mechanism of resistance to free chlorine is production of slime layers, Enterobacter and Klebsiella may well be adapted to grow in distribution systems, and other coliforms could be incorporated in the slime layers that they produce. REMOVING URANIUM BY CURRENT MUNICIPAL WATER TREATMENT PROCESSES,
Oak Ridge National Lab., TN.
S. K. White, and E. A. Bondietti.
Journal of the American Water Works Association, Vol. 75, No. 7, p 374-380, July, 1983. 4 Tab, 25 Ref.

Descriptors: *Water treatment, *Uranium, Drinking water, Lime, Hydrogen ion concentration, Alum, Carbonates, Minerals.

Raw, intermediate-stage, and treated water samples from 20 public water supplies were analyzed for uranium content. The results indicate that current municipal water treatment practices are not effective in handling uranium. Raising the pH to 9.5 or greater (as in lime treatment) will result in uranium loss by precipitation, the amount of loss varying with the sample. Alum may be effective in uranium removal, but dosage will vary according to carbonate concentration and pH. Such experimentation suggests that uranium removal can be accomplished by water treatment processes with modification of pH, chemical dosages, or both; variation in the order in which treatments are carried out; and special attention to coeffects that exist because of the mineral content of the water or combinations of chemicals used in treatment. (Baker-IVI)

ACTION OF CHLORINE DIOXIDE ON AQUATIC ORGANIC MATERIALS DURING THE DISINFECTION OF DRINKING WATER,
Hadassah Medical School, Jerusalem (Israel). Environmental Health Lab.
Ch. Rav-Acha, R. Blits, E. Choshen, A. Serri, and B. Limoni.
Journal of Environmental Science and Health, Vol. A18, No. 5, p 651-671, September, 1983. 6 Fig, 6 Tab, 33 Ref.

Descriptors: *Chlorination, *Drinking water, *Organic matter, Disinfection, Trihalomethanes, Chlorine dioxide.

LIBRARY U. OF I. URBANA-CHAMPAIGN

Measurements were made of the total organic halogens produced in the National Water Carrier of Israel after disinfection with chlorine dioxide. Compared to chlorine, chlorine dioxide formed only a very small amount of chlororganic compounds. Mixtures of chlorine and chlorine dioxide which have been reported to reduce the concentrations of both the chlorinated organics as well as the chlorite ions produced by chlorine dioxide, were found not to be of significant benefit due to the fact that high bromide concentrations are present in the National Water Carrier. Thus high ratios of chlorine dioxide to chlorine are needed to reach a significant reduction in trihalomethane concentration. The amount of trihalomethanes can be satisfactorily reduced, however, when chlorine dioxide is introduced a few hours before chlorine. A comparison between chlorine and chlorine dioxide in regard to reaction with a series of polycyclic aromatic hydrocarbons showed that the chlorine dioxide reactions were more unique. While the highly carcinogenic compounds such as benz(a)pyrene and 1,2-benzanthracene react with chlorine dioxide much more rapidly than with chlorine, other hydrocarbons, such as naphthalene and fluoranthene react very little with chlorine dioxide but easily react with chlorine. Findings suggest that in contrast to chlorine which reacts by few possible pathways, chlorine dioxide reacts mainly as a one-electron acceptor. The main organic by-products of chlorine dioxide seem to be aldehydes, ketones and quinones, beside low molecular weight carboxylic acids. Although aldehydes and carboxylic acids are usually regarded as monitoxic materials, the toxicity of quinones and some keto-aldehydes are still largely unknown. (Baker-IVI)

POWER OF GRAVITY CUTS WATER COSTS,
Raymar Engineering, Inc., Walnut Creek, CA.
M. S. Fohrman.
Water Engineering and Management, Vol. 1. 130, No. 7, p 26-28, July, 1983. 4 Fig.

Descriptors: *Water resources development, *Gravity filters, *Water treatment facilities, Lake Hemet, California, Topography.

The Lake Hemet Municipal Water District in California has incorporated unique geographic features at its recently completed Theodore H. Eggen Filtration Plant. This was done by using a gravity flow system as part of the process train. As a result, total power requirements are less than 20 hp. The automated 6 million gallon per day plant required only one hour of supervision each day. Three raw water sources feed the treatment plant. In winter the water comes from the North Fork of the San Jacinto River and from Strawberry Creek. As winter flows diminish, water is diverted from the South Fork of the San Jacinto, which originates from Lake Hemet Dam. All three flows converge into an overflow diversion structure situated more than a mile upstream from the plant site. Filtration is accomplished by four filters in parallel arrangement. To take further advantage of the hilly terrain, a hydroelectric generation facility has been proposed. The system will then produce enough power to accomodate all the electrical needs of the plant with any surplus being sold to the electrical utility. (Baker-IVI)

CONTROL OPTIONS FOR NITRATES AND FLUORIDES,
Black and Veatch, Dallas, TX.
W. J. O'Brien.
Water Engineering and Management, Vol. 130, No. 7, p 36-38, 51, July, 1983. 4 Fig, 4 Tab, 7 Ref.

Descriptors: *Nitrates, *Fluorides, *Drinking water, Water quality, Standards, Public health.

Nitrate and fluoride concentrations in drinking water supplies must be controlled for sound public health reasons, primarily for the protection of two population groups - infants, and children up to the age of 14, respectively. Water containing concentrations of nitrate nitrogen greater than 10 mg/l has been known to produce a disorder known as methemoglobinemia in infants less than three months old. Fluoride controls are in force to prevent dental fluorosis, a discoloration or mottling that occurs when teeth are being formed. Strong base anion exchange resins have usually been the preferred method for removing nitrate from water supplies. The major problem is a fouling of the resin when ferrous iron is present in the raw water. Presently it is not economical to use anion exchange resins for removal of fluoride as resins exhibit no selectively for this element. Excess lime softening is frequently used and the amount of fluoride that can be removed by this method is proportional to the quantity of magnesium in the water. (Baker-IVI)
W84-01915

EFFECT OF THE 1981/82 WINTER ON WATER SUPPLIES,
P. S. Turton.
Weather, Vol. 38, No. 10, p 314-318, October, 1983. 1 Fig, 4 Tab, 5 Ref.

Descriptors: *Water supply, *Freezing, *Water distribution, Weather, Cold regions, Pipes, Water mains, Leakage.

After the severe winter of 1962/63 the water industry in England and Wales experienced little difficulty during wintertime for the next 15 years. However, 1978/79 and 1981/1982 reminded both the public and the water industry that water pipes are vulnerable to severe frost. Most of the water industry's resulting difficulties in these times were local inconveniences, a heavy burden on staff and an increase in operating costs. Generally the industry coped well in the 1981/82 winter although if the cold had been unbroken the strain would have been considerable. If the recent cold winters herald a longer period of frequent cold winters then the cumulative effect on water mains could be significant and hinder the authorities programs of enhanced leakage control. The mechanisms by which cold weather affects water mains is not well researched or understood as effort is being given toward discovering and repairing leaks. The public must learn to take adequate precautions to prevent burst pipes if they wish to help avoid temporary disruption of the supply of water in winter. (Baker-IVI)
W84-01991

REMOVAL OF BACTERIA FROM WATER BY ADHESION TO CROSS-LINKED POLY(VINYLPYRIDINIUM HALIDE),
Kyoto Inst. of Tech. (Japan). Dept. of Chemistry.
N. Kawabata, T. Hayaski, and T. Matsumoto.
Applied and Environmental Microbiology, Vol. 46, No. 1, p 203-210, July, 1983. 7 Fig, 4 Tab, 10 Ref.

Descriptors: *Disinfection, *Poly(vinylpyridinium halide), Organic carbon, Escherichia coli, Salmonella, Streptococcus, Staphylococcus, Pseudomonas, Adhesion, Bacteria, Water treatment.

Cross-linked poly(vinylpyridinium halide) was found to have a novel and remarkable ability to remove bacteria from water. For example, when 10 g (wet weight) of cross-linked poly(N-benzyl-4-vinylpyridinium bromide) was contacted with 20 ml of suspensions of Escherichia coli (97,000 to 9.7 x 10 to the 7th power /ml), Salmonella typhimurium (8.0 x 10 to the 6th power to 1.1 x 10 to the 7th power /ml), Streptococcus faecalis (5.0 x 10 to the 7th power /ml), Staphylococcus aureus (8.1 x 10 to the 7th power /ml), and Pseudomonas aeruginosa (320,000/ml) under stirring in sterilized physiological saline at 37 degrees C, 99% of the viable cells of these bacteria were removed in 2 to 6 h. When suspensions of these bacteria (100,000 to 10,000,000 cells per ml) were passed through a column (20 mm by 100 cm) of cross-linked poly(N-benzyl-4-vinylpyridinium bromide) at 37 degrees C with a flow rate of 0.8 to 1.4 bed volumes per h, 97 to 100% of the viable cells were eliminated from the suspensions during the treatment. Mechanistic studies demonstrated that cross-linked poly(vinylpyridinium halide) irreversibly captured these bacteria alive during the treatment. That is, total organic carbon was removed during the treatment, and the bacteria which adhered to the resin proliferated on the bacterial medium. The adhesi capacity was estimated to be 10 to the 10th ce per g (dry weight). Total organic carbon was al removed even when the bacteria were killed heat treatment before the column studies. INACTIVATION OF HEPATITIS A VIRU AND INDICATOR ORGANISMS IN WATE BY FREE CHLORINE RESIDUALS,
National Inst. for Water Research, Pretoria (Sout Africa).
W. O. K. Grabow, V. Gauss-Muller, O. W. Prozesky, and F. Deinhardt.
Applied and Environmental Microbiology, Vo 46, No. 3, p 619-624, September, 1983. 3 Fig, Tab, 29 Ref.

Descriptors: *Hepatitis A virus, *Chlorinatio *Disinfection, Drinking water, Water treatmen Viruses, Bacteriophage, Bacteria, Indicators, Viru inactivation.

Hepatitis A virus (HAV) and selected indicato organisms were mixed together in chlorine demand-free buffers at pH 6, 8, or 10 and expose to free chlorine residuals, and the survival kinetic of individual organisms were compared. HAV wa enumerated by a most-probable-number dilutio assay, using PLC/PRF/5 liver cells for propaga tion of the virus and radioimmunoassay for it detection. At all pH levels, HAV was more sensi tive than Mycobacterium fortuitum, coliphag V1(representing a type of phage common in som sewage-polluted waters), and poliovirus type 2 Under certain conditions, HAV was more resistan than Escherichia coli, Streptococcus faecalis, coli phage MS2, and reovirus type 3. It was always more resistant than SA-11 rotavirus. Evidence i presented that conditions generally specified fo the chlorine disinfection of drinking-water supplies will also successfully inactivate HAV and that HAV inactivation by free chlorine residuals can reliably be monitored by practical indicator systems consisting of appropriate combinations of suitable indicators such as coliform and acid-fast bacteria, coliphages, the standard plate count, and fecal streptococci. Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 2, p 39-47, 1983. 8 Tab, 32 Ref.

Descriptors: *Water treatment, *Chemical treatment, *Toxicity, *Environmental effects, Water treatment chemicals.

After a description of some of the important toxicological and ecological testing procedures, toxicological and ecological data, available in the literature, provided by the manufacturers or measured in our own laboratories are presented in a tabular fashion for some typical water treatment chemicals and their formulations. In addition, the chemical composition of those substances contained in several selected water treatment products are given, grouped according to their function and combinations as used. The areas of application, dosages, methods of application, as well as pH values and classification based upon regulations governing water treatment materials, are also given in tabular form. Based upon these data, the products and the individual components are toxicologically and ecologically assessed and an estimation as to the toxicological and ecological risks in their use is attempted. . Water Quality Control

STORATION OF AQUIFERS,
sephson.
ironmental Science and Technology, Vol. 17, 8, p 347A-350A, August, 1983. 2 Fig.

criptors: *Aquifer management, *Groundwater ution, Groundwater management, Water resources development, Water treatment, Drinking water, Granular activated carbon.

Once an aquifer becomes contaminated there are three basic courses of action which may be taken: forbid use of the aquifer and obtain alternative supplies; attempt to rehabilitate it; or continue to use the aquifer but treat the water before use. The first step toward groundwater restoration is knowing the extent, thickness, rate of spread, and contents of a contamination plume. Conceivably, the zone of contamination could be both overlain and underlain by clean water. That is why the utmost care must be taken, when wells are screened, to account for the three-dimensional aspect of the plume when a monitoring well network is planned. The monitoring scheme used must consider plume spread in two horizontal and one vertical direction over time. A properly installed well monitoring system must monitor the entire thickness of the aquifer being studied. The cost of such wells could range from $400 to $3000 each. Costs for sample analysis could come to $200-$1500 per sample. Once a contaminated plume is identified and mapped, a treatment scheme is needed. Treatment alternatives are considered and then bench and pilot scale studies are conducted. Granular activated carbon (GAC) is a frequently adopted treatment for contamination episodes involving organic chemicals. In some cases multimedia filtration is carried out before GAC treatment as a precaution. In others, air stripping is used to reduce the amount of volatile organics. Aeration, catalyzed chemical oxidation and GAC adsorption have also been used to remove organic solvents including chloroform, carbon tetrachloride, and other low-molecular weight chlorinated hydrocarbons. Pressurized gas aeration followed by direct incineration is undergoing evaluation in place of air stripping. Microbes and an organics removal approach involving powdered activated carbon are being tested with activated sludge. Both reclamation of contaminated groundwater and aquifer recharge can present technical and legal problems. A major factor of the feasibility of groundwater reclamation is cost. (Baker-IVI)

PROTECTING WATER SUPPLY AQUIFERS IN AREAS USING DEEP-WELL WASTEWATER DISPOSAL,
CH2M Hill Southeast, Inc., Gainesville, FL.
J. I. Garcia-Bengochea.
Journal of the American Water Works Association, Vol. 75, No. 6, p 288-291, June, 1983. 1 Fig, 2 Tab, 4 Ref.

Descriptors: *Deep-well injection, *Wastewater disposal, *Water pollution prevention, *Disposal wells, Groundwater pollution, Water quality control, Monitoring, Geohydrology, Florida.

The geohydrology of Florida allows deep-well injection of treated wastewater in some areas if care is taken to assure protection of overlying aquifers used for public water supplies. The state is underlain by a series of groundwater-bearing strata separated by thick and practically impervious layers. In the southern part of the peninsula, the deeper strata contain saltwater in highly transmissive zones that are effectively separated from the overlying freshwater strata. This allows for the high-rate injection of pretreated wastewater into the deeper saltwater zones. Precautions must be taken during construction, operation, and ultimate abandonment of the disposal wells to assure containment of injected wastes. When a disposal well is abandoned, complete sealing of the casing from the bottom to the surface is required. Monitoring water quality and potentiometric levels in adjoining aquifers is essential during construction, operation, and ultimate abandonment of the facility. (Moore-IVI)

SODA ASH TREATMENT OF A STRONTIUM-90-CONTAMINATED GROUNDWATER SEEP,
Oak Ridge National Lab., TN. Environmental Sciences Div.
B. P. Spalding, and I. L. Munro.
Journal of Environmental Quality, Vol. 12, No. 3, p 366-373, July-September, 1983. 3 Fig, 3 Tab, 17 Ref. DOE contract W-7405-ENG-26.

Descriptors: *Strontium-90, *Groundwater pollution, *Water pollution control, Radioactive waste disposal, Soda ash, Seep water, Chemical precipitation, Conductivity, Hardness, Oak Ridge National Laboratory.

A Sr-90 contaminated groundwater seep on the perimeter of a low-level radioactive solid waste disposal area at the Oak Ridge National Laboratory (ORNL) was treated by burying 315 kg of soda ash in the groundwater flow path leading to the seep, and placing 45 kg of soda ash on the surface of the seep. The concentration of Sr-90 in the seep water fell from an average of 7000 Bq/L to 900 Bq/L for the 90 d after burial, followed by a period of gradual rise back to pretreatment levels over the next 100 d. The electrical conductivity and pH of the seep water increased following soda ash burial, while water hardness fell. Hardness was highly correlated (r = 0.84) with Sr-90 concentrations over the entire 2-year observation period, indicating the similar behavior of Sr-90 and soluble Ca and Mg. This in situ softening of, and Sr-90 precipitation from, the seep water was achieved by coprecipitation of Sr-90 with Ca(Mg)CO3 until the buried soda ash was depleted by dissolution in the groundwater. The soda ash treatment of groundwater seeps appears to be most practical as an interim technique for those situations requiring an immediate, but temporary, corrective action. During this limited but effective period, more permanent corrective actions could be planned at the source of contamination. The electrical conductivity, pH, and hardness of the larger surface stream, into which this seep discharges, were not affected by the soda ash burial, most likely due to the approximately 2000-fold dilution effected by this stream. HISTORY OF ENVIRONMENTAL WATER QUALITY MANAGEMENT IN SCOTLAND,
Clyde River Purification Board, East Kilbride (Scotland).
D. Hammerton.
Journal of the Institution of Water Engineers and Scientists, Vol. 37, No. 4, p 336-346, August, 1983. 22 Ref.

Descriptors: *Water quality, *Water management, Scotland, Legislation, Regulations, Surface water, Pollution control.

Historically the pollution of the aquatic environment has been as severe in Scotland as anywhere in the U.K. The development of an effective pollution control system has been painfully slow, as in England and Wales, and has resulted in a very different administrative framework. It is remarkable that two distinct methods of managing the water cycle should have been evolved within one small nation but there are sound geographical and political reasons for this and the Scottish system appears well suited to the needs of the country. Changes occurring during 1975 provided a major new impetus for local government and for the river purification boards. The previous 324 sewerage authorities had been replaced by 9 regional councils, which were also the strategic planning authorities, thus greatly simplifying and improving the consultative process. The regional council all have highly qualified headquarters staff and thus are able to provide a management service to ensure

that sewage works function at maximum efficiency. In order for the water authorities to meet the obligations of the Control of Pollution Act 1974, Part II, significant upgrading of their scientific expertise in all aspects of oceanography will be required. (Baker-IVI)

MODELING INLAND WATER QUALITY USING LANDSAT DATA,
Australian National Univ., Canberra. Dept. of Engineering Physics.
D. J. Carpenter, and S. M. Carpenter.
Remote Sensing of Environment, Vol. 13, No. 4, p 345-352, September, 1983. 1 Fig, 1 Tab, 11 Ref.

Descriptors: *Model testing, *Water quality, *Lakes, Turbidity, Algal growth, Remote sensing, Satellite technology, Landsat, Australia.

The water quality parameters turbidity and algal pigment concentration of freshwater lakes have been modeled and predicted using Landsat multispectral scanner data as multiple linear predictors. Satellite data for an area in South East Australia from seven occasions during 1978 and 1979 were used along with concurrent ground-based measurements from sampling sites on three lakes covering a wide range of water quality regimes. Date-independent models for turbidity and algal pigment were obtained using the satellite multispectral data and the water quality data from up to 21 sampling sites on one lake on six occasions. The sun elevation at the time of satellite overpass was included in the models to account for differences between dates, and the time of sample collection was included to compensate for diurnal variations in pigment fluorescence. These models were used to successfully predict these water quality parameters for this lake on a new occasion and for the two other lakes on three occasions. (Author's abstract)

BURIED PIPE SYSTEM FOR CONTROLLING EROSION AND SEDIMENT LOSS ON IRRIGATED LAND,
Agricultural Research Service, Kimberly, ID. Snake River Conservation Research Center.
D. L. Carter, and R. D. Berg.
Soil Science Society of America Journal, Vol. 47, No. 4, p 749-752, July-August, 1983. 2 Fig, 2 Tab, 13 Ref.

Descriptors: *Erosion control, *Sediment control, *Furrow irrigation, Irrigation effects, Sediment erosion, Sedimentation basins, Tailwater, Agricultural runoff.

A new system comprised of a buried pipe, with riser inlets from the surface at intervals, along the lower end of furrow-irrigated fields was designed, installed, and evaluated on 21 fields to determine its effectiveness as an erosion and sediment loss control system for irrigated land. The system utilizes small sediment collection ponds with the riser inlets from the buried pipe serving as overflow outlets for the ponds. This system corrects convex-shaped field ends caused by erosion and solves an energy related erosion problem common on furrow-irrigated land. During the first season, these system removed from 80 to 95% of the sediment from runoff water and collected from 4.1 to 40.5 Mg/ha from 12 fields on irrigated land where detailed data were collected. All systems performed without problems and all convex end problems except one were corrected the first season. After the convex ends are corrected, the system continues to reduce sediment loss. This new system eliminates the tailwater ditch, puts more land into crop production, reduces weed problems, and prevents the usual problems associated with a wet tailwater ditch. The buried pipe erosion and sediment loss control system is a major advance in the control of erosion and sediment loss on irrigated land. (Author's abstract)

COMPUTATION AND REPORTING OF DISSOLVED GAS LEVELS,
California Univ., Davis. Dept. of Civil Engineering.
J. E. Colt.
Water Research, Vol. 17, No. 8, p 841-849, August, 1983. 4 Tab, 33 Ref.

Descriptors: *Dissolved oxygen, *Water quality, *Dissolved gases, Seawater, Temperature effects, Salinity, Nitrogen, Argon, Water vapor.

Provisional standards are proposed for the computation and reporting of dissolved gas levels in freshwater and seawater. Total gas pressure should be reported in terms of excess pressure, while component gases such as nitrogen, argon, oxygen and water vapor should be reported in terms of partial or excess pressure. Barometric pressure, dissolved oxygen, water temperature and salinity must also be reported. Recent work in hyperbaric physiology has shown that the initial bubble formation depends on excess pressure and therefore excess pressure is the best predictor of the danger from supersaturation. The concentration of component gases should be expressed as partial pressure in mm Hg rather than percent saturation. Recommended formulae for the computation of gas saturation levels are presented. REGIONALIZATION OF WATER QUALITY IN THE UPPER FRASER RIVER BASIN, BRITISH COLUMBIA,
Inland Waters Directorate, Vancouver (British Columbia). Water Quality Branch.
P. H. Whitfield.
Water Research, Vol. 17, No. 9, p 1053-1066, September, 1983. 11 Fig, 4 Tab, 19 Ref.

Descriptors: *Water quality, *Cluster analysis, Fraser River, River basins, British Columbia, Water analysis.

Uniformity of water quality in the Upper Fraser River basin was examined using cluster analysis. Substantial variations in water quality were observed within the basin. The differences were largely related to the geology of the watersheds. Differences in water quality were more pronounced among the tributaries than along the mainstream of the Fraser River. The mainstream of the river could be considered to have three distinct reaches where water quality properties were relatively constant. Cluster analysis was a useful technique for establishing similarities and differences for both the tributaries and the mainstrem stations. Good agreement was obtained between the results of cluster analysis and examination of spatial concentration differences. The results of the two methods differed in cases where the rate of change in concentration appeared to be important. The cluster analysis technique used did not consider these changes. Inclusion of derived variables, reflecting the rate of change among sequential stations could improve the discrimination of this technique. The assignment of uniform water quality objectives or stream standards would not be practical due to the substantial differences in water quality observed between adjacent groups of stations. COST-EFFECTIVE REGULATORY OPTIONS FOR WATER QUALITY LIMITED STREAMS,
Wisconsin Univ.-Madison. Dept. of Economics.
M. H. David, and E. L. David.
Water Resources Bulletin, Vol. 19, No. 3, p 421-428, June, 1983. 2 Fig, 2 Tab, 7 Ref. Dept. of Commerce grant NA800AA-D-0086.

Descriptors: *Permits, *Water pollution control, *Water quality standards, *Costs, Wisconsin, Regulation, Aeration, Transferable discharge permits, Rolling averages, Variable permits, Flow regulation.

With the pressure from industries and municipa ties to reduce the waste water treatment co associated with the permit limits needed to att the goals of the Clean Water Act, attention h turned ways of introducing flexibility into the re ulations without sacrificing the water quality goa Wisconsin is the first state to have adopted variety of options from which dischargers m choose when meeting their water quality requi ments. These options were developed for the e press purpose of minimizing the costs and maxim ing the flexibility of the point source water quali regulations while ensuring that permitted di charge would not violate the water quality stan ards. Options that the state has made available dischargers include: variable permits; rolling ave ages; transferable discharge permits; instream ae ation; and flow regulation. Variable permits a probably the most cost-saving of the options b cause they reduce the average time period durin which the most stringent limits must be met fro 52 wk/yr to several weeks or months in th summer. Rolling averages adddress the inequity o limiting each discharger on the assumption that a others will be discharging at their maximum pe mitted level. Transferable permits are importan because they allow equity considerations to b separated from efficiency. The option to increas the dissolved oxygen or flow of the river reduc somewhat the costs of abatement. Aeration has th additional advantage that it can be used in eme gencies to maintain standards. A mixture of perm options is likely to be the most cost-effective an satisfactory strategy for meeting water qualit standards. Variable permits, some form of cluste permits or rolling averages, transferable permit and instream aeration appear to be the most impor tant options to use in meeting waste load alloca tions on the major rivers. SOIL EROSION AWARENESS AND USE OF CONSERVATION TILLAGE FOR WATER QUALITY CONTROL,
Iowa Agricultural and Home Economics Experi ment Station, Ames.
P. F. Korsching, and P. J. Nowak.
Water Resources Bulletin, Vol. 19, No. 3, p 459-462, June, 1983. 4 Tab, 13 Ref.

Descriptors: *Soil erosion, *Farming, *Erosion control, *Attitudes, Behavior, Water pollution control, Conservation tillage, Iowa.

Water pollution through loss of topsoil from farmland continues to be a major problem, despite nearly 50 years of providing farmers technical and financial assistance for soil and water conservation. The technology for controlling erosion and water pollution is available, but farmers have been slow in implementing control practices. Using a random sample of 249 farmers from central Iowa, the relationship is examined between awareness of a soil erosion problem and the use of conservation tillage. Average farm size of the operators in the sample was 470 acres, and row crops, corn and soybeans, were the predominant crops. There was a high level of awareness of the need for erosion control, but a rather low level of awareness of the problems of soil erosion and water quality. Approximately 96% of the operators considered the Midwest and Iowa to have a medium or serious soil erosion problem, whereas only about 72% and 54%, respectively, saw a medium or serious problem in their own community or on their own farm. There is a strong relationship between the use of conservation tillage and perceived severity of erosion on the farm. Awareness of a soil erosion problem affects the use of conservation tillage, and awareness can be enhanced by experimental educational strategies such as the development and implementation of a soil and water conservation plan. r pollution control, Nitrogen oxides, Sulfur
de, Oxides, Sulfur, Nitrogen.

ifying substances present in the atmosphere of
r enviromental significance are oxides of sulfur and nitrogen. Atmospheric sulfur occurs in compounds in gas, liquid and solid phases. Residence times for atmospheric sulfur dioxide are estimated at 1 to 2 days. Wet deposition of sulfur compounds, mainly in aerosol form as sulfate, occurs by in-cloud and below-cloud scavenging. Control strategies for reducing acidifying substances emitted to the atmospheric will need to concentrate on one or more stages of fuel use: before burning, low N and S fuel; during burning, staged, catalytic or coal-limestone combustion; waste gas venting, flue gas desulfurization and ammonia injection. HYPOLIMNETIC AERATION OF A NATURALLY EUTROPHIC LAKE: PHYSICAL AND CHEMICAL EFFECTS,
British Columbia Ministry of the Environment, Vancouver. Fisheries Research and Technical Services Section.
K. I. Ashley.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 40, No. 9, p 1343-1359, September, 1983. 16 Fig, 2 Tab, 52 Ref.

Descriptors: *Aeration, *Hypolimnion, *Eutrophic lakes, Water quality control, Thermal stratification, Turbidity, Nitrification, Oxygenation, Phosphorus, Carbon dioxide, Eutrophication, Fish winterkill, Nutrients.

A small naturally eutrophic lake was divided in half with a plastic curtain, and a hypolimnetic aerator was installed and operated in the experimental half for one year. Hypolimnetic aeration had no effect on thermal stratification during the ice-free season but circulated the entire experimental half under ice cover. Aeration increased hypolimnetic turbidity via reduced detrital sedimentation but did not affect epilimnetic transparency. Hypolimnetic oxygen concentrations were increased as was oxygen consumption as both sediment and water column oxidation of organic material was enhanced. Hypolimnetic ammonia concentrations were reduced and sufficient oxygen was added for nitrification to occur. Internal phosphorous loading and hypolimnetic orthophosphate concentrations were reduced but aerobic P regeneration increased. Aeration vented accumulated CO2 from the hypolimnion and decreased hypolimnion calcium, magnesium, bicarbonate, and orthophosphate content via calcium carbonate phosphate coprecipitation. Management applications of hypolimnetic aeration include reduction of internal nutrient loading for eutrophication control, improvement of water quality for domestic use, and prevention of fish winterkill. MEET ENVIRONMENTAL NEEDS FOR REFINERY EXPANSIONS,
Bechtel Great Britain Ltd., London (England).
M. W. Askew, S. A. Tapley, and R. A. Killick.
Hydrocarbon Processing, Vol. 62, No. 10, p 65-70, October, 1983. 2 Fig, 2 Tab, 1 Ref.

Descriptors: *Industrial wastes, *Environmental impact statement, Oil, Sulfides, Phenols, Heavy metals, Ammonia, Chlorine, Bioaccumulation.

Unique problems are associated with refinery expansions. Sources of wastes are often uncontrolled and their effects on the environment are seldom known. The environmental impact statement should include present environmental status, target environmental status, type and quantity of prospective emissions, impact of emissions, emission control, control technology, emission and environmental status monitoring, and economics and cost effectiveness. The expansion situation calls for additional items to be considered such as existing environmental impacts and status, source characteristics and quantification of existing emissions, possibilities for the integrated control and management of emissions, existing with new emissions within new pollution control systems, and the impact of environmental standards in determining the scope of an expansion project. In regarding aqueous emission problems, oil is the major concern along with sulfides and sulfur bearing organics, phenols, heavy metals, ammonia, free chlorine, salinity, solids in suspension, temperature, chronic and acute toxicity, and potential bioaccumulation of materials. BACTERIA AND ACIDIC DRAINAGE FROM COAL REFUSE: INHIBITION BY SODIUM LAURYL SULFATE AND SODIUM BENZOATE,
Ohio State Univ., Columbus. Dept. of Microbiology.
P. R. Dugan, and W. A. Apel.
Applied and Environmental Microbiology, Vol. 46, No. 1, p 279-282, July, 1983. 2 Fig, 15 Ref. OWRT grant B073-Ohio.

Descriptors: *Mine wastes, *Acid mine drainage, *Chemautotrophic bacteria, *Anionic detergents, Sodium lauryl sulfate, Sodium benzoate, Detergents, Water pollution control.

Coal mine drainage represents a major environmental problem in regions where high-sulfur coal is mined and mineral wastes are deposited. The problem results from exposure of pyritic minerals, found in intimate association with coal and other minerals, to the combined effects of atmospheric oxygen, moisture, and acidophilic Thiobacillus bacteria. The application of an aqueous solution of sodium lauryl sulfate and sodium benzoate (at approximately 60 parts of detergent per million parts of refuse by weight) to the surface of high-sulfur coal refuse resulted in the inhibition of iron- and sulfur-oxidizing chemoautotrophic bacteria and in the decrease of acidic drainage from the refuse, suggesting that acid drainage can be abated in the field by inhibiting iron- and sulfur-oxidizing bacteria. PREDICTING COLIFORM CONCENTRATIONS IN UPLAND IMPOUNDMENTS: DESIGN AND CALIBRATION OF A MULTIVARIATE MODEL,
Saint David's Univ. Coll., Lampeter (Wales).
D. Kay, and A. McDonald.
Applied and Environmental Microbiology, Vol. 46, No. 3, p 611-618, September, 1983. 4 Fig, 6 Tab, 40 Ref.

Descriptors: *Multivariate analysis, *Coliforms, *Reservoirs, *Watershed management, Regression analysis, Escherichia coli, Water quality, Mathematical models, Recreation, Water treatment, Bacteria, Catchment area, Water supply, Thruscross Reservoir, Fewston reservoir, England.

A multiple regression model was designed to predict concentration of Escherichia coli and total coliforms in two upland impoundments, Thruscross and Fewston reservoirs, which supply water to the city of Leeds (England). The multivariate approach has improved predictive capability over previous univariate linear models because it includes predictor variables for the timing and magnitude of hydrological input to the reservoirs and physiochemical parameters of water quality. A calibrated model for any particular site would give the catchment manager an information base by which to limit certain recreational activities during periods or at locations of peak bacterial loading. The multivariate approach would also allow the manager of a treatment plant of limited capacity to predict the period and severity of stress by a mixture of environmental conditions producing high bacterial loadings, and to investigate appropriate countermeasures. Regression analysis can provide a useful management tool in multiple-use catchment areas. (Moore-IVI)

Descriptors: *Aquaculture, *Ammonia, *Hydrogen ion concentration, Carbon dioxide, Aeration, Nitrates, Nitrification, Calcium.

In aquaculture, feed remnants and excrement, as well as metabolic products from the fish, cause an intensive development of NH4(+), which is in equilibrium with the toxic NH3, depending on proton concentration and temperature. If the pH of productive water is raised, then there is an increase in the amount of NH3 released, so that the equilibrium shifts in favor of the ammonia. The object of this investigation was to follow the influence of the pH value of water throughout the mineralization process of the feed, by using CO2 gas and by applying montmorillonite covered with H(+) or with Ca(2+); also, to study the effects these measures had on the release of NH3 and on other water parameters. Five test variants were chosen. The lowest release of NH3 was recorded with the application of CO2 gas. The other parameters measured (pH, CSB, Ges-N, NH4(+) and NO3(-)) also produced lower values with this method. The highest concentration of NH3 was found in the varient using ventilation. The exchange of NH4(+)ions for H(+) and Ca(2+) ions had a diminishing effect on the release of NH3. The Ca(2+) montmorillonite clearly had a positive effect on the development of nitrate. This could be due to the adsorption of a pH range which was optimal for nitrification and thus favorable for Ca(2+) supply. (Author's abstract)

OPTIMAL DESIGNS OF BRANCHED WATER SUPPLY NETWORKS,
Indian Inst. of Tech., Bombay. Dept. of Civil Engineering.
A. V. Chiplunkar, and P. Khanna.
Journal of Environmental Engineering, Vol. 109, No. 3, p 604-618, June, 1983. 4 Fig, 2 Tab, 21 Ref.

Descriptors: *Water supply development, *Decision making, Design criteria, Civil engineering, Water supply, Gravity flow, Mathematical studies.

A rational procedure for the optimization of branched water supply networks is developed in closed form, using the Lagrangian Multiplier Technique. The solutions are workable on calculators and obviate the requirement of computers in optimal design and successive reevaluations. Case studies on complete gravity and direct pumping systems are presented to illustrate the solution procedure. Specific examination is made of a simplified approach developed by Swamee to multibranch systems, considering each branch to be initially independent, thereby requiring one Lagrangian multiplier, while estimating the multiplication factor for that branch and later combining all branches by choosing the maximum multiplication factor for common sections. The design identified through this simplified approach has been compared with the exact design considering all the branches simultaneously, thereby requiring as many Lagrangian multipliers as the branches. Despite a marginal difference in the theoretical optimal diameters by the two approaches, the final design remains unchanged due to the requirement of discrete commercial pipe sizes. A complete algorithm for the estimation of theoretical optimal diameters along with a procedure for rounding off to the commercial sizes to minimize the difference in the design by the two approaches is also presented. RESOURCE ALLOCATION TO INTERRELATED PROJECTS,
Ben-Gurion Univ. of the Negev, Beersheba (Israel).
A. Mehrez, and Z. Sinuany-Stern.
Water Resources Research, Vol. 19, No. 4, p 876-880, August, 1983. 1 Fig, 4 Tab, 14 Ref.

Descriptors: *Decision making, *Model studies, Multiattribute utility function, Water resources development, Project planning.

A multiattribute utility function was used to specify the decision-maker's preferences, along with a zero-one budget model, to solve the problem of selecting among interrelated multiobjective long-range projects. Increasing the number of projects increases the complexity of the problem. The advantages of the model for relatively small problems are demonstrated by a case study dealing with a subset of Israeli water development projects for 1981. The concept of partitioning the utility function into attributes has proven useful for the decision maker, as it allows him to test the contribution of the sets of projects to each attribute separately. The possible negative impact of a project on an attribute is also considered. (Baker-IVI)

MODELING TELLS THE HYDRAULIC STORY,
Miller Engineering, Inc., King of Prussia, PA.
T. C. Miller, Jr.
Water Engineering and Management, Vol. 130, No. 9, p 34-35, August, 1983. 1 Fig.

Descriptors: *Model studies, *Hydraulic equipment, Water distribution, System analysis, Planning, Water management.

Hydraulic modeling can be an invaluable asset for optimizing existing or planned water distribution systems. In an aging water system, the need for hydraulic modeling is most commonly recognized when a major system improvement is being planned to a system that has become too complex to comprehend. In a new water system, the engineer has many improvement options available to him, and can use modeling to overview the scope, timing and cost effectiveness of each. Capital improvement planning is perhaps the most dramatic example of the benefits of hydraulic modeling. Basic steps to be considered prior to developing a hydraulic model include understanding how the system operates, identifying the scope of the questions that will be asked of the model, acquiring adequate source data, combining the acquired source data with the hydraulic modeling program, and identifying how the hydraulic model will be cost-effectively maintained and updated. Several case histories are briefly reviewed to discuss the practical application of hydraulic modeling to existing water systems and new water systems. (Baker-IVI)

ment, Social aspects, Evaluation, Decision makin

Local or project level planning occurs within mo
federal water resources programs. Such plannin
involves both federal and local participants, an
commonly involves a range of interest groups. It
necessary to know what goals these participan
believe the planning process ought to achieve i
order to design planning procedures which wi
meet their expectations. Social judgment analys
was used to elicit those goals for respondents wh
had participated in one of five different federa
water resources programs, in one of the five diffe
ent roles. Respondents also evaluated the extent t
which the planning activities in a recent project i
which they had participated had actually attaine
the posited goals. The respondents believed tha
responsiveness to local problems was significantl
more important than resolving conflicts or increas
ing public understanding. A fourth goal, achievin
national objectives, was believed to be less impor

an the other three. No significant differences se goal evaluations were associated with the of program in which the respondents had pated. However, there were significant dif- es associated with the respondent's role in anning process. Respondents' ratings of the veness of actual planning projects varied by rogram and respondent role. isions in the rules and procedures for perform- cost-benefit analyses of federal water projects ude a requirement that nonstructural and water conservation measures be incorporated into economic assessments of projects. Project analyses will now proceed as if water supplies were allocated most effectively, that is, to their highest valued uses. A related requirement provides that the net benefits of any project should now be valued using willingness to pay measures. Water conservation activities include: reducing the level or altering the time pattern of demand by metering, leak detection and repair, rate structure changes, regulation on use, education programs, and drought contingency planning; modifying management of existing water development and supplies by recycling, reuse, and pressure reduction; and increasing upstream watershed management and conjunctive use of ground and surface waters. A specific cost-benefit methodology was constructed to accomodate the revisions in rules and procedures. In addition to being consistent with federal mandates, this technique offers important advantages over the traditional requirements approach to water supply planning. The advantages of this approach are largely the result of utilizing water demand functions, together with water supply functions, in the evaluation procedure. Use of demand functions is recommended because these functions implicitly incorporate pricing as well as those technical opportunities for water conservation which are known to have positive net benefits. Use of demand functions also permits willingness to pay measures to be calculated for specific projects. (Moore-IVI)

ESTIMATION OF DIRECT IRRIGATION BENEFITS,
Colorado State Univ., Fort Collins. Dept. of Economics.
R. K. Sampath.
Water Resources Bulletin, Vol. 19, No. 3, p 469-476, June, 1983. 2 Fig, 1 Tab, 6 Ref.

Descriptors: *Irrigation, *Mathematical models, *Benefits, Water demand, Population dynamics, Estimating, Water supply.

For optimal allocation of resources, it is critical to arrive at proper estimations of direct benefits created by irrigation projects. The traditional and new methods of estimation of direct benefits from irrigation development were reviewed, highlighting the theoretical implications of these methods. Comprehensive formulas were derived to show the extent of bias in these methods. Since irrigation benefits occur over a long period of time, the dynamic aspects such as shifts in demand and supply functions for commodities due to changes in income, population, and technology cannot be overlooked. Ignoring these important dynamic aspects will lead to underestimation or overestimation of direct benefits. Shifts in demand that occur over time due to population growth are incorporated in a theoretical model for estimation of direct irrigation benefits. Formulas were derived for the estimation of total surplus and its distribution between consumers and producers. (Moore-IVI)

NATURE OF LONG RUN COST SAVINGS DUE TO WATER CONSERVATION,
Army Engineer Waterways Experiment Station, Vicksburg, MS.
T. M. Walski.
Water Resources Bulletin, Vol. 19, No. 3, p 489-498, June, 1983. 8 Fig, 1 Tab, 10 Ref.

Descriptors: *Water conservation, *Foregone costs, Water resources development, Water supply facilities, Construction costs, Maintenance costs, Costs, Economic aspects, Capital.

Savings in capital, operation, and maintenance cost of new water supply facilities are referred to as 'long run foregone costs.' Any conservation measure leads to reduction of water use or loss; however, significant long run foregone costs are realized only when reductions in size or delays in construction of facilities result. In order to accurately evaluate these costs it is necessary to know which facilities are affected and how they are affected (eliminated, downsized, or delayed). The effects of several levels of conservation on long run foregone costs for an actual study are presented and some easy to use equations are derived that may be used to calculate such savings. Long run foregone costs resulting from water conservation are more dependent on the size and construction year of new water supply facilities than on the reduction in water use or loss. The foregone cost functions are not only frequently nonlinear, but they may be discontinuous. This is especially true when the decision to build or not to build a large facility at a fixed date must be made. If a facility affected by conservation is scheduled to be built within roughly five years of the beginning of the planning period, it is more economical to downsize the facility. If it is to be built later in the planning period, it is more economical to delay construction. (Moore-IVI)

6C. Cost Allocation, Cost Sharing, Pricing/Repayment

PRICE BEHAVIOR IN THE WATER MARKET OF NORTHEASTERN COLORADO,
Colorado State Univ., Fort Collins. Dept. of Economics.
R. L. Gardner, and T. A. Miller.
Water Resources Bulletin, Vol. 19, No. 4, p 557-562, August, 1983. 2 Fig, 2 Tab, 14 Ref.

Descriptors: *Prices, *Water market, *Colorado-Big Thompson water, Water shares, Irrigation water, Industrial water, Municipal water, Colorado.

Past prices of Colorado-Big Thompson water shares were analyzed using an asset pricing model which incorporated the growth rate in real returns to irrigation water and the value of potential urban water uses. A real growth rate in the returns to irrigation water was estimated at 5.3%. Nevertheless, market values for water shares have exceeded capitalized agricultural values since 1969. Historically, urban use potential was heavily discounted, but the implicit discount rate fell rapidly in the last decade. The expectation that water shares will eventually be sold to municipal or industrial consumers now appears to be reflected fully in water prices. The real value for an acre-foot share of Colorado-Big Thompson water is not expected to rise much above its 1980 real market value of $2,895. Prices in this range appear to fully reflect the willingness-to-pay for municipal and industrial water. Continuation of the present situation of high nominal interest rates and relatively low inflation rates will likely keep water prices below this level. (Moore-IVI)

DISTRIBUTIONAL ISSUES IN WESTERN MUNICIPAL AND INDUSTRIAL WATER SUPPLY,
Utah Univ., Salt Lake City. Dept. of Economics.
J. R. Miller, and D. A. Underwood.
Water Resources Bulletin, Vol. 19, No. 4, p 631-640, August, 1983. 1 Fig, 4 Tab, 12 Ref.

Descriptors: *Financing, *Repayment, *Municipal water, *Industrial water, *Irrigation water, Central Utah Project, Bonneville Unit, Utah, Cost allocation, Water allocation, Water policy.

Financing and repayment provisions of western water projects effect transfer of income among federal taxpayers, electric power users, local water users, and property owners. The Bonneville Unit of the Central Utah Project (CUP) is used as a case study in the distribution of municipal and industrial water costs. Bonneville Unit water is developed in two basins, 164,500 acre-ft or 53% in the Unita Basin and 148,500 acre-ft or 47% in the Bonneville Basin. Only 27,900 acre-ft of project water, less than 9%, remains in the Uinta Basin. The project is

at least nominally an irrigation project, as 66% of the water is committed for that purpose. The distribution of costs among taxpayers and water users in different political/geographical jurisdictions, and how this distribution is affected by water law, cost allocation procedures, and the choice of revenue source for local repayment of reimbursable costs were examined. Irrigation water is heavily subsidized, both in terms of the zero interest provision and the reliance on Basin Fund revenues for irrigation repayment. Some counties bear a portion of the cost of municipal and industrial water without receiving any of it. In counties which receive water, costs are shared between water users and property taxpayers. Except for the counties receiving no water, there is a close correspondance between the financial contribution and water received. The interest subsidy on municipal and industrial water repayment of implementation present water policy, the lack of open debate on water issues is unfortunate. (Moore-IVI)

PRICING IRRIGATION WATER IN DEVELOPING COUNTRIES,
North Carolina State Univ. at Raleigh. Dept. of Economics and Business.
J. A. Seagraves, and K. W. Easter.
Water Resources Bulletin, Vol. 19, No. 4, p 663-672, August, 1983. 1 Fig, 1 Tab, 21 Ref.

Descriptors: *Pricing, *Developing countries, *Irrigation, Marginal cost, Economic aspects, Water supply development.

Alternative combinations of water pricing and regulations are possible in allocating irrigation water. The best combination will depend on the value of water, ability to control deliveries, desire to subsidize agriculture, ownership traditions, crops grown, return flows, drainage problems, staff training, ability to collect fees, and the number of farmers. Marginal cost pricing is explained and identified with a way of thinking about administered prices rather than a rigid system. Alternative pricing schemes are illustrated and some conclusions are offered. Four different pricing systems can be distinguished: direct charges based on measured volumes; direct charges per share of the flow in a stream or canal; direct charges per acre irrigated; and indirect charges on crop outputs marketed or on other inputs purchased. Regulations and prices for irrigation water will reflect conflicting goals. Institutions which are appropriate for regulating and/or pricing irrigation water depend on a number of factors besides the goals. For economic efficiency reasons, it is desirable to base administered prices on the marginal cost of acquiring more water, or on its opportunity cost in alternative uses. However, it is often contended that prices based on marginal costs will be too high for farmers with low incomes. Marginal cost pricing of water has special relevance to seasonal shortages and chronic over-irrigation. Institutions for the management of water from irrigation canals are affected by the ease with which the flow can be measured. When flows are uncertain, shares rather than volumes of the water can be allocated to individual farms. It is not worthwhile to seek greater physical efficiency in all cases. The irrigation system that is economically most efficient depends on the value of water and other variables. (Baker-IVI)

6D. Water Demand

WATER FOR LAS VEGAS METROPOLITAN AREA,
URS Co., Las Vegas, NV.
D. A. Haselhoff.
Journal of Environmental Engineering, Vol. 109, No. 3, p 700-712, June, 1983. 2 Fig, 7 Tab.

Descriptors: *Water demand, *Las Vegas, *Nevada, *Water supply development, Water conservation, Population growth, Groundwater, Water reuse, Arid areas, Urban areas, Water management, Economic aspects.

The Las Vegas area is one of the most arid parts of the driest state in the nation. It is among the fastest growing areas in the nation, and water supplies must be sought and managed to meet the demands of this growth. Water suppplies currently available include groundwater, Colorado River water, and wastewater reuse. New sources of water supply include groundwater stored in adjacent valleys and potentially vast quantities of water stored in deep-carbonate aquifers. Water demand functions were developed by different user classes including residential, commercial, industrial, civic, agricultural and non-agricultural irrigation, and system losses. These functions can assist other planners in determining water use in arid climates. The Las Vegas metropolitan area can manage water resources to meet needs for at least the next 50 years. Unique characteristics of the valley required assessment of all components of the water resource system so that water would be economically available for growth. Projected supply exceeds projected demand through at least the year 2020 considering various factors that can reduce available supply. Projected demand can be reduced by successful water conservation programs. An implementation program was developed to provide economical water by protecting existing supply, managing that supply wisely to meet peak demands, and exploring for new water supply sources when present sources are no longer adequate to meet demands of growth. (Moore-IVI)

MULTICRITERIA ANALYSIS OF WATER ALLOCATION IN A RIVER BASIN: THE TCHEBYCHEFF APPROACH,
Princeton Univ., NJ. Dept. of Civil Engineering.
N. P. Greis, E. F. Wood, and R. E. Steuer.
Water Resources Research, Vol. 19, No. 4, p 865-875, August, 1983. 7 Fig, 5 Tab, 23 Ref.

Descriptors: *Water allocation, *Multicriteria analysis, Computer models, Delaware River Basin, Seasonal water allocation, Linear optimization, Water demand, Comsumptive use.

A new interactive multiple objective methodology is applied to the seasonal water allocation problem. Linear optimization and filtering procedures are combined within a multiobjective framework in order to identify nondominated solutions associated with randomly sampled criteria vectors. The procedure samples from the entire nondominated set, not just the set of nondominated extreme points, by computing the nondominated criteria vector that is closest to an ideal criteria vector according to a weighted Tchebycheff metric. Unlike many other multicriteria methods, the Tchebycheff procedure is capable of finding solutions of highest utility which may not correspond to extreme point solutions. The procedure is applied to the problem of water allocation in the Delaware River Basin where a large number of conflicting objectives, including environmental objectives, compete for the available supply. The basin has large consumptive needs, and demand for water is gradually outstripping supply, causing frequent, often severe shortages in several sectors. (Moore-IVI)

engthy trial in the Supreme Court of Nova
ia may influence design of future stormwater
ems in Canada. The developer of a 203 ha area
an upstream developer and the provincial
artment of transportation, claiming real and
cipated damages from increased flows and vol-
s of stormwater. The plaintiff claimed that it
entitled to have the defendants reduce quanti-
and rates of flow, or to have costs of enlarging
ystem paid by the defendants. The Court con-
ed that the defendants were not required to
rict flows to pre-development levels as long as
used natural watercourses and did not cause
r natural capacity to be exceeded. The down-
am owner is obligated to accept the increased
s, to design watercourse modifications to ac-
odate these flows, and to base his determina-
of flows on a 100 year rainfall event. An
rect result of the court case, and of the situa-
that produced it, was the creation of the
ifax County Storm Drainage Task Force. Most
he problems that led to the court case would
e been avoided if the policies and criteria had
n in place to guide the activities is both up-
am and downstream developers. If cost-effec-
implementation of stormwater policies and
eria is to be achieved, preparation of drainage
ter plans and development of cost-sharing
hanisms are essential. (Moore-IVI)

IORITY POLLUTION RIGHTS: ADAPTING
LLUTION CONTROL TO A VARIABLE EN-
RONMENT,
Colorado Univ., Boulder. Dept. of Economics.
C. W. Howe, and D. R. Lee.
Land Economics, Vol. 59, No. 2, p 141- 149, May, 1983. 1 Fig, 13 Ref.

Descriptors: *Water pollution control, *Legal aspects, Appropriation, Environment, Waste disposal.

Variability in the assimilative capabilities of the environment and in demands for the waste disposal services of the environment pose difficult problems for pollution control systems. A feature is proposed for pollution rights systems that is expressly designed to deal with environmental variability in an economically efficient manner. The system is referred to as a priority pollution rights system (P.P.R.S.). It is an adaptation of the long standing system of appropriations doctrine found in western U.S. water law. The P.P.R.S. has much greater flexibility and makes more efficient use of privately held technological and cost information than alternative instruments of control in adapting pollutant discharge rates to variations in the assimilative capabilities of the environment. Possibilities of undesirable forms of strategic behavior in the market warrent further study, but such possibilities exist under all instruments. Successful experience with priority water rights in the western U.S. bodes well for similar systems in the field of pollution control. (Baker-IVI)

EX POST FACTO ANALYSIS OF THE REGIONAL ECONOMIC IMPACT OF EXPENDITURES FOR RESERVOIR RECREATION,
Texas Agricultural Experiment Station, College Station. Dept. of Recreation and Parks.
J. H. Gramann.
Journal of Environmental Management, Vol. 16, No. 4, p 357-367, June, 1983. 5 Tab, 14 Ref.

Descriptors: *Reservoirs, *Recreation, *Economic impact, Economic justification, Water resources development, Management, Prediction, Illinois.

A comparison is made between the predicted and actual economic impact of recreation expenditures at a reservoir in the state of Illinois. Although originally designed for multiple uses, the reservoir is justified primarily in terms of recreation. Expenditure data collected from a representative sample of reservoir visitors are utilized in an input-output analysis to determine the direct, indirect, and induced effects of these expenditures on personal income in the two counties in which the reservoir is located. Recreation expenditures directly and indirectly accounted for 1.3% of total personal income in the two-county region, which contrasts sharply with the optimistic forecasts of civic boosters and project planners. Several criticisms of pre-reservoir economic impact assessments are made. Among these are their focus on total recreation expenditures rather than on income derived from expenditures, and the failure of project supporters to distinguish spending by local from non-local visitors. Both practices inflated considerably the predicted impact of recreation expenditures. Input-output matrices for the area show the retail sector of the economy to be relatively independent of other economic sectors. Although the impact of recreation expenditures is felt mostly in retail enterprises, the low level of retail development, together with that sector's structural independence, indicates that overall economic impacts will continue to be small. EFFECTS OF IMPOUNDMENTS ON DOWNSTREAM BED MATERIALS OF TWO UPLAND RIVERS IN MID-WALES AND SOME ECOLOGICAL IMPLICATIONS OF SUCH EFFECTS,
Ministry of Agriculture and Water Development, Lusaka (Zambia).
J. Scullion.
Archiv fur Hydrobiologie, Vol. 96, No. 3, p 329-344, March, 1983. 3 Fig, 4 Tab, 39 Ref.

Descriptors: *Rivers, *Environmental effects, *Impoundments, Flow rates, Macroinvertebrates, Physical properties, Substrates, Wales.

Physical properties of substrate such as particle size composition, gravel porosity, organic matter content, permeabilities, and apparent water velocities of two regulated and two unregulated rivers were studied over a period of about one year. During this period these properties did not change appreciably, despite substantial flow fluctuations of unregulated rivers. There were few significant differences between regulated and unregulated rivers despite the elimination or reduction of summer and autumn spates by regulation. The most ecologically important effects of regulation on the macroinvertebrate fauna would seem to be the occlusion of bed surfaces by deposits, rich in iron and manganese derived from storage reservoirs, and changes in the temperature regime. The effects of regulation on salmonid egg survival are also discussed. (Baker-IVI)

ATTEMPTED RECONSTRUCTION OF THE FAUNA OF LARGE RIVERS AND FLOOD PLAINS OF EUROPE (VERSUCH EINER REKONSTRUKTION DER FAUNA EUROPAISCHER STROME UND IHRER AUEN),
E. J. Fittkau, and F. Reiss.
Archiv fur Hydrobiologie, Vol. 97, No. 1, p 1-6, May, 1983. 6 Ref.

Descriptors: *Rivers, *Fauna, *Flood plains, Aquatic life, Nutrients, Flooding, Europe.

The fauna of the large European rivers has been destroyed before it was possible to carry out a full investigation. The destruction of this fauna has been brought about not only through canalization of the rivers for ship traffic but also through the introduction of industrial effluents and the cultivation of the flood plains. The flood plains, with their numerous small and large lotic and lenitic waters, together with the river constitute an ecological entity. The habitats 'Fluss-Aue' are continuously formed and preserved through flooding and have been the place producing the basic nutrient component for the zoocoenoses of the river and the hatching area for migrating fishes. The waters of the flood plains, by their enormous continuity, in time, become of great significance for the evolution of the aquatic fauna. (Author's abstract)

ANALYSIS OF DISSOLVED OXYGEN CONCENTRATIONS IN TAIL WATERS OF HYDROELECTRIC DAMS AND THE IMPLICATIONS FOR SMALL-SCALE HYDROPOWER DEVELOPMENT,
Oak Ridge National Lab., TN. Environmental Sciences Div.
G. F. Cada, K. D. Kumar, J. A. Solomon, and S. G. Hildebrand.
Water Resources Research, Vol. 19, No. 4, p 1043-1048, August, 1983. 3 Fig, 2 Tab, 14 Ref. DOE contract W-7405-eng-26.

Descriptors: *Hydroelectric power, *Dissolved oxygen, *Tailwater, Dam effects, Environmental effects, Water quality, Seasonal variation, Small-scale hydropower.

Dissolved oxygen concentrations in reservoir tail waters from operating hydroelectric sites were paired with dissolved oxygen measurements from nearby downstream Geological Survey water quality stations. A total of 65 small-scale hydroelectric sites were selected, of which four did not have both winter and summer dissolved oxygen data; 74 large-scale hydroelectric sites were paired with nearby water quality stations, three of which did not have both winter and summer data. These data were used to calculate probabilities of noncompliance (PNC's), that is, the probabilities that dissolved oxygen concentrations in the discharge waters of operating hydroelectric dams will drop below 5 mg/l. The continental states were grouped into eight regions based on geographic and climatic similarities. Most regions had higher mean PNC's in summer than in winter, and summer PNC's were greater for large-scale than for small-scale hydropower facilities. PNC's were generally less than 0.05 during the winter months, regardless of generating capacity. Cumulative probability distributions of PNC also indicated that low dissolved oxygen concentrations in the tail waters of operating hydroelectric dams are phenomena largely confined to sites with large-scale facilities. PNC's are not a function of electrical capacity per se but rather appear to be dependent upon factors related to capacity, such as reservoir depth. Potential dissolved oxygen problems are unlikely to hinder small-scale hydropower development in the U.S. (Moore-IVI)

RECREATION AT DRINKING WATER RESERVOIRS IN MASSACHUSETTS: A SURVEY OF WATER MANAGERS,
Massachusetts Univ., Amherst.
L. R. Klar, Jr., and A. Ghirin.
Water Resources Bulletin, Vol. 19, No. 3, p 477-481, June, 1983. 5 Tab, 12 Ref. OWRT WRA 107-MASS.

Descriptors: *Reservoirs, *Recreation, *Massachusetts, *Water pollution sources, Drinking water, Fishing, Water management, Municipal water, Attitudes, Regulations, Watersheds.

The recreational use of public drinking water reservoirs in Massachusetts is quite limited, particularly in comparison to other parts of the country. A survey was conducted of 51 municipal water supply managers in Massachusetts. Water officials were found to advocate highly restrictive views. Of the agencies owning or controlling their own reservoirs, 62.5% had policies prohibiting all recreational activities on their reservoirs or surrounding watershed areas. Fishing was the most common activity allowed among agencies permitting recreation. Managers from agencies owning or controlling no reservoirs were more likely to favor recreation to a significant degree. No officials said that recreation was an insignificant source of water supply pollution, and opinions were not found to be related to respondents' exposure to the literature on the topic. The majority of managers were not familiar with the literature assessing the impact of recreation on water supply reservoirs. (Moore-IVI)

NEW COURSE FOR THE NILE,
A. Charnock
New Scientist, Vol. 100, No. 1381, p 285-288, 27 October, 1983. 9 Fig.

Descriptors: *Water resources development, *Enviromental effects, *Social change, Canals, Nile River, Sudan, Jonglei Canal.

A 50 year old plan to divert the Nile away from the swamps of south Sudan is nearing completion. The Jonglei Canal should improve communications and agriculture, but the effects on the local populations are not clear. The Canal will divert a quarter of the White Nile's waters in a 360 km channel that will bypass the Sudd swamps, 600 km south of Khartoum where more than half of the Nile's flow evaporates every year. The canal should shrink the swamps and their floodplains, and present the first man-made barrier to a cycle of pastoral migration which has existed for thousands of years. Opportunities to expand health services will be improved. The major concern is the possible spread of the schistosome parasite. (Baker-IVI)

CHANGES IN THE SEDIMENTARY FLUXES IN LAKE WALCHENSEE BY ANTHROPOGENICALLY CAUSED ALTERATIONS OF ITS CATCHMENT AREA (VERANDERUNGEN IM SEDIMENTATIONSGESCHEHEN DES WALCHENSEES DURCH ANTHROPOGENE EINGRIFFE IN DAS EINZUGSGEBIET),
C. Steinberg, E. Hammerle, and J. Meilhammer.
Zeitschrift fur Wasser und Abwasser Forschung, Vol. 16, No. 2, p 48-54, 1983. 11 Fig, 14 Ref.

Descriptors: *Environmental effects, *Sediment transport, *Diversion, Catchment areas, Lake Walchensee, Upper Isar River, Rissbach Brook, West Germany, Calcium, Phosphorus, Chlorophyll, Plant pigments, Wastewater, Agricultural runoff, Water resources development, Land development.

Diversion of the Upper Isar River (since 1924) and the brook Rissbach (since 1950) into Lake Walchensee (Upper Bavaria, Germany, F.R.) for energy purposes enlarged the lake's catchment area from 59.3 sq km to 783.6 sq km. The catchment area of the Upper Isar River contributes 510 sq km. Since the diversions drain into different bights of the lake, their effects on biogeochemical cycling in the lake can be studied by determination of the sedimentary fluxes in the corresponding bight. The annual sedimentary fluxes of calcium, phosphorus and plant pigments (chlorophyll a and degradation products) for the two bights receiving the diversions are compared with the flux in a third bight not influenced by a diversion. The diversion of the Upper Isar River increased the sedimentary flux of calcium from 30 to 900 g/sq m/a Ca. This value is more or less constant since the mid fifties. The phosphorus flux increased from 100 to 1,000-1,500 mg/sq m/a P and reached maximum values of 2,500 to 7,400 mg/sq m/a since the end fifties. These increases are due to the development of various tourist facilities, e.g. mountain-railways etc., as well as increase in wastewater quantities, and agricultural intensification in the catchment area. The sedimentatary flux of plant pigment reflects this situation. Prior to 1924, less than 6.0 mg/sq m/a pigment were sedimented, between 1924 and 1957, 30 to 80 and thereafter up to 330 mg/sq m/a. The diversion of the brook Rissbach into the lake led to a sedimentary flux of calcium of 1 to 3 kg/sq m/a with decreasing rates in the past five years. This is also true for the phosphorus sedimentary flux since about 1971: in the most recent layers the data oscillate around 2,000 mg/sq m/a P. This value is only about one third of the flux influenced by the River Isar. There is a steady increase in the deposition of plant pigments since 1960. (Moore-IVI)

WATER CENTRE DEVELOPS GROUND RADAR,
J. Bell.
New Scientist, Vol. 98, No. 1363, p 870-871, 2 June, 1983. 2 Fig.

Descriptors: *Ground radar, *Sewer systems, Leakage, Pipelines, Collapse, Mapping.

Five thousand of the big holes that appear in Britain's roads every year may be blamed on collapsed or blocked sewers. Ground radar, to spot the voids that sewers fall into, is now in the experimental prototype stage. The theory is that if radar could detect voids outside the sewers (often caused by burst sewers leaking and washing soil away) then it should be possible to prevent some of the expensive collapses. The prototype, which consists of two antennas in a perspex tube, is a variable frequency machine. It has to be variable because radar penetration underground may change randomly according to the presence or absence of gaps, stones, water, sand, and so on. Damage to sewers may also be prevented by electronic mapping, thus avoiding the loss of sewer and water mains over the years through the lack of accurate records as to their original placement. OPTIMUM DESIGN OF SMALL RESERVOIRS (TANKS),
California Univ., Davis. Dept. of Civil Engineering.
O. J. Helweg, and P. N. Sharma.
Water Resources Research, Vol. 19, No. 4, p 881-885, August, 1983. 2 Fig, 2 Tab, 9 Ref.

Descriptors: *Design criteria, *Reservoirs, Tanks, India, Arid regions, Construction, Model studies.

Small reservoirs, called tanks, are part of traditional water transport methods in the semiarid tropics of India and other countries. While considerable investment is being planned to construct more of these tanks, no investigation has been made to determine the most efficient design for them. Assuming the most efficient operating policy and tank location, there are two separable optimization problems in designing a small tank or reservoir irrigation system. The first deals with optimal tank dimensions and the second with optimal storage capacity. The size of a tank irrigation system may either be constrained by the catchment area available for producing runoff and/or the limited area suitable for irrigation. An example of a small reservoir irrigation system for Hyderabad region in south India is presented as a demonstration of the method of design. (Baker-IVI)

FLOOD PLAIN AND MAIN CHANNEL FLOW INTERACTION,
Birmingham Univ. (England). Dept. of Civil Engineering.
D. W. Knight, and J. D. Demetriou.
Journal of Hydraulic Engineering, Vol. 109, No. 8, p 1073-1092, August, 1983. 19 Fig, 2 Tab, 14 Ref.

Descriptors: *Flood plains, *Channel flow, Shear stress, Shear force, Model studies, Hydrologic models, Channel roughness.

Experimental results are presented concerning the discharge characteristics, the boundary shear stress and boundary shear force distributions in a compound section comprising of one rectangular main channel and two symmetrically disposed flood plains. The experiments were conducted in a 15 m flume, 610 mm wide. Two flood plains, 76 mm high and 229 mm wide were added, creating a symmetrical cross section with a center channel 152 mm wide and 76 mm deep. The apparent shear force acting on the vertical interface between one flood plain and the main channel is strongly depth dependent. The apparent shear forces are always positive, indicating that the flood plain retards the main channel flow. Equations are presented giving the proportion of the total flow which occurs in the various sub areas. The division of flow based on linear proportion of the areas is inadequate on account of the interaction between the flood plain and main channel flows. The experimental results apply only to the case in which the flood plains have the same roughness as the main channel and are symmetrically disposed. (Moore-IVI)

MODELLING OF DISCONTINUITIES THROUGH DIPOLE DISTRIBUTION,
Thessaloniki Univ., Salonika (Greece). Lab. of Hydraulics and Hydraulic Works.
E. Sidiropoulos, C. Tzimopoulos, and P. Tolikas.
Applied Mathematical Modelling, Vol. 7, No. 5, p 306-310, October, 1983. 6 Fig, 10 Ref.

Descriptors: *Dipole distribution, *Dams, *Sheet-piles, *Discontinuities, *Flow, Mathematical models, Boundary element methods, Singularities.

The problem of the flow under a dam with a sheet-pile in its foundation is treated as a characteristic example of the introduction of dipoles in order to model the discontinuity in the potential function across the cut-off wall. Dipole singularities were used in order to account for the presence of a sheet-pile in the flow. The method is not restricted to a single pile. The same procedure can be applied to the case of more sheet-piles and of arbitrary inclination. The width of the sheet-piles is taken to be zero and the dipoles are placed along the axis of the sheet-piles. A linear boundary element was placed at the tip of the sheet-pile. The coefficients of the linear system of equations are all given in analytical form and no partition into zones is necessary. Very good agreement with analytical results is demonstrated, the mean absolute relative deviation being of the order of 4%. With the insertion of a linear element at the tip of the sheet-pile it was possible to obtain the same value of the potential on both faces of the sheet-pile at that point. (Moore-IVI)

TURBULENCE STRUCTURE OF DILUTE DRAG-REDUCING POLYMER SOLUTIONS IN A RECTANGULAR OPEN CHANNEL FLOW,
Yamaguchi Univ. (Japan). Dept. of Chemical Engineering.
H. Usui, and Y. Sano.
AIChE Journal, Vol. 29, No. 4, p 611-617, July, 1983. 11 Fig, 20 Ref.

Descriptors: *Drag, *Open channels, *Polymers, *Turbulent flow, Velocity, Drag reduction, Bursting, Discharge capacity, Eddies.

The drag reduction phenomenon in a rectangular open channel flow was examined by measuring the longitudinal velocity by means of a laser Doppler anemometer. Drag reduction was detected using 50 and 100 ppm polymer additives (polyethylene oxide). Statistical analysis of the fluctuating velocity showed that the most significant effect of the polymer additive on the large-scale turbulent motion appeared in the turbulent core of an open channel flow. The scale of bursting phenomenon was enlarged by the polymer additive, and the typical ejection process was detected as the remarkable negative fluctuating velocity throughout the buffer and turbulent core regions except near the free surface. The maximum increase of discharge capacity was 40% of the Newtonian fluid case. The skewness factor of polymer solutions showed anomalously high negative value at $y(+) = 70$ to 120. The corresponding flatness factor was much larger than that of water. These observations were interpreted as an increased scale of the large eddy motion in polymer solutions and as the results of suppression of sweep process because of the existence of free surface. DESIGN OF IN-LINE JET INJECTION BLENDERS,
Auburn Univ., AL. Dept. of Civil Engineering.
O. Guven, and L. Benefield.
Journal of the American Water Works Association, Vol. 75, No. 7, p 357-363, July, 1983. 4 Fig, 1 Tab, 26 Ref.

Descriptors: *Mechanical equipment, *Design criteria, Blenders, Injection, Water treatment.

Available information on the initial mixing characteristics of turbulent jets in crossing pipe flow is reviewed, and criteria is given for the optimum design of in-line jet injection blenders. A previously proposed design procedure for centrally injected jets is discussed, and an analysis is presented to indicate how this procedure can be improved. Both the velocity ratio and the diameter ratio should be considered as design variables in the design of in-line jet injection blenders. Optimum conditions for small diameter ratios are characterized by a constant value for the momentum ratio, whereas the optimum momentum ratio for large diameter ratios is not a constant and depends on the diameter ratio. The central jet injection scheme has several advantages as a rapid mix method compared with the side jet injection scheme, and experimental studies are needed to quantify the optimum conditions for the case of central jets. GEOPHYSICAL METHOD OF EVALUATING EXISTING EARTH EMBANKMENTS,
Davenport/Hadley Ltd., Golden, CO.
L. M. Hadley.
Bulletin of the Association of Engineering Geologists, Vol. 20, No. 3, p 289-295, August, 1983. 10 Fig.

Descriptors: *Earth dams, *Seismic properties, *Measuring instruments, Soil mechanics, Dam failure, Dams, Safety, Seismographs.

Earth embankments need periodic inspection and monitoring, especially, if settlement or damage is suspected. Currently, earth embankment condition is evaluated through visual inspection and analysis of data from instrumentation such as piezometers and inclinometers. A program to evaluate the condition of existing earth embankments using geophysical methods was developed and is currently being used as part of a safety evaluation of existing earth embankments in the western United States. The geophysical method utilizes the 'common offset' seismic refraction technique which emphasizes areas of change. Seismic lines are run along the dam axis and toe. Anomalous areas, if any, are targeted for drilling. This technique was applied to about 15 dams. A base line data file will be established for all the major earth dams in the United States. New seismic lines could then be run after a dam has undergone an event such as an earthquake and the two sets of data compared. More detailed information will be gained from the seismic data as the program continues and drilling data become available for direct comparison. If a correlation is found between seismic characteristics and physical properties, the amount of drilling required in future studies of settlement at earth embankments should be greatly reduced. RECONNAISSANCE ESTIMATES OF SUBSIDENCE ALONG SALT-GILA AQUEDUCT, ARIZONA,
Water and Power Resources Service, Sacramento, CA. Mid-Pacific Region.
N. P. Prokopovich.
Bulletin of the Association of Engineering Geologists, Vol. 20, No. 3, p 297-315, August, 1983. 16 Fig, 1 Tab, 32 Ref.

Descriptors: *Subsidence, *Aqueducts, Design criteria, Canals, Construction, Groundwater depletion, Arizona, Salt-Gila Aqueduct.

A new approach was recently tested for prediction of subsidence along the Salt-Gila Aqueduct. This concrete-lined aqueduct is 104 km long and follows basin margins eastward of Phoenix, Arizona. Prominent subsidence started with an intensification of ground-water pumpage in the 1940's. Available annual leveling data along the alinement extend from 1971-1978. It was assumed that the 1971-76 subsidence amounted to 20% of past subsidence occurring during overdraft of ground water. Experience with other studies indicated that future residual subsidence along the aqueduct caused by pre-1976 overdraft could be equal to the amounts of past subsidence. Estimated declines of ground water between 1976 and 2005 and between 1976 and 2020 were calculated to be respectively 16% and 22% of the 1923-76 decline in the northern portion and 65% and 112% in the southern portion of the alinement. These ratios were used for estimates of post-1976 subsidence caused by pre-2005 and pre-2020 overdrafts (assuming constant ratios between subsidence and overdraft). Maximum estimated subsidence was 1.91 m for 2005 and 2.09 m for 2020. However, this subsidence will not be achieved for many years after 2005 and 2020. The amount of actual 1976-2005 and 1976-2020 subsidence was estimated using an assumed 30-year half-life of residual subsidence. The values were up to 0.96 m for the year 2005 and up to 1.30 m for the year 2020. These rough estimates were made at a cost of less than $10,000 and verified the sophisticated costly preconstruction estimate. A similar comparison of 2-3 independent estimates appears to be a sound approach for all large projects. (Author's abstract).

INEXPENSIVE TECHNIQUE TO MEASURE SUBSIDENCE ALONG CANALS,
Water and Power Resources Service, Sacramento, CA. Mid-Pacific Region.
N. P. Prokovich, and H. J. Hall.
Bulletin of the Association of Engineering Geologist, Vol. 20, No. 3, p 317-323, August, 1983. 7 Fig, 110 Ref.

Descriptors: *Canals, *Subsidence, *Irrigation canals, Soil mechanics, Water depth, Delta-Mendota Canal, Friant-Kern Canal, California.

Irrigation canals, particularly in dry areas, are frequently affected by land subsidence. Monitoring of such subsidence is essential for operation, maintenance and possible rehabilitation of canals. Periodic leveling of canal alignments is expensive, time consuming, and locally may be obscured by tectonic movements. An inexpensive and rapid method for the measurement of subsidence by determining the depth of water in canals, as applied in the Mid-Pacific Region, is described below. Large canals are divided into pools by check structures which are designed to control or to stop water flow by the manipulation of check gates. For subsidence studies, depth of water in a canal is measured at the upstream and downstream ends of all pools during standstill time with check gates completely closed. Actual depth of water may be different in different pools, but the difference of depth at downstream and upstream ends of each pool corresponds to the invert gradient of a pool and is constant in stable areas. The difference changes, however, in pools affected by subsidence. These changes reflect the amount of subsidence during the time interval between consecutive sets of measurements. In particularly long pools additional depth measurements can be made at convenient strucure sites, such as bridges. This method was used for rough measurements of subsidence in the Delta-Mendota and Friant-Kern Canals in California. (Author's abstract)

MEASURING THE CONTRIBUTION OF LAND AND WATER TO AGRICULTURE,
Idaho Univ., Moscow. Dept. of Agricultural Economics.
R. B. Long.
Water Resources Bulletin, Vol. 19, No. 4, p 613-617, August, 1983. 6 Tab, 3 Ref.

Descriptors: *Irrigation effects, *Agriculture, *Dry farming, Idaho, Wheat, Barley, Hay, Regression analysis, Income.

A paucity of yield data does not allow direct measurement of the contribution from irrigated crop agriculture, nor does it allow evaluation of the contributions from livestock which are dependent upon irrigated feed. In order to isolate the dryland and irrigated contributions for wheat, barley, and hay, county data for southern Idaho (34 counties) were assembled for irrigated acres, dryland acres, and total production. Regression analysis was performed with total output a function of dryland acres and irrigated acres. Regression results indicate that 80% of Idaho farm income is associated with irrigation, and that 75% of the farm income in the 17 western states is associated with irrigation. For the United States as a whole, 13.7% of the total cropland (irrigated land) produced 41.3% of all cash receipts from farming in 1978. If 14% of the land can produce 40% of the value of production, perhaps 35% of our land can produce all our food and fiber needs. Such an allegation has several implications in terms of the adequacy of our land and water resources. Irrigated agriculture is far more important on the basis of dollars of output than one might expect by simply observing and comparing dryland and irrigated acreage data. The role of technology has r
been exhausted, especially if current dryland are
could be made to produce like those that
already irrigated. (Moore-IVI)

sion, *Critical shear stress, Dam stability, Pipi
failure, Dam failure, Dam filters, Clay, Dam co
Design criteria.

The current design practice for filters in earth a
rock fill dams permits the use of widely grad
sand-gravel mixtures as filter materials. The use
these criteria without consideration of the erodi
lity characteristics of the core material and cra
potential of the filter has caused near failure a
total failure of several dams. A new method
presented for quantifying the erodibility of so
based on the use of critical shear stress, Tc, dev
oped due to hydraulic flow in the cracked zone
a dam. Critical shear is influenced by the clay ty
and amount, composition of pore and erodi
fluid, and structure of the soil. The use of Atte
berg Limits to classify erosion characteristics
inadequate. A direct correlation between the cri
cal shear stress required to cause erosion and t
piping failure of several dams was found. Co
fines with Tc values less than 4 dynes/sq cm a
one of the contributing factors causing piping fa
ure of dams. Even if the clay is erodible, it
possible to prevent dam failure is adequate prote
tive filters are provided. Correctly quantifying er
dibility and carrying out filtration tests using t
eroded fines and proposed filter material is recon
mended for the safe design of protective filte
The degree of clogging of the pores in the filt
material may be used to evaluate its cracking su
ceptibility. (Moore-IVI)

STRESS AND SEEPAGE ANALYSIS O EARTH DAMS,
Schnabel Engineering Associates, Bethesda, MD
G. C. Li, and C. S. Desai.
Journal of Geotechnical Engineering, Vol. 10
No. 7, p 946-960, July, 1983. 14 Fig, 3 Tab, 21 Re

Descriptors: *Earth dams, *Stress analysis, *Seep
age, *Dam stability, *Earthworks, Soil mechanics
Mathematical models, Embankments, Soil satura
tion, Dam construction.

A finite element procedure is developed for stres
seepage and stability analysis of dams and earth
banks. The soil behavior is modeled by using linea
elastic, nonlinear elastic and plasticity based laws
The seepage analysis is based on a residual flo
scheme involving saturated and unsaturated zone
in which the original mesh remains invarian
during the transient flow and iterations. By usin
the same mesh for stress analysis including sequen
tial embankment construction, it is possible to su
perimpose directly the effects of external and seep
age forces. If appropriate pressure-permeability re
lations are available, it is possible to incorporat
effects of partial saturation during construction.
is also possible to include in the analysis changes i
the dam geometry during the deformation process
The procedure has been found to provide satisfac
tory correlation with analytical solutions and fiel
observations for a number of problems. It can b
useful and appropriate for nonlinear stress, seepag
and stability analysis of dams and earth banks

UNSTEADY SEEPAGE ANALYSIS OF WAL LACE DAM,
Georgia Inst. of Tech., Atlanta. School of Civi
Engineering.
M. M. Aral, and M. L. Maslia.

LIBRARY U. OF I. URBANA-CHAMPAIGN

nal of Hydraulic Engineering, Vol. 109, No. 6, 9-826, June, 1983. 12 Fig, 1 Tab, 27 Ref.

riptors: *Embankments, *Earthworks, *Seep- Mathematical models, Unsaturated flow, Satu- flow, Dam piping, Dam filters, Drainage, pressure, Finite element analysis, Pumped ge, Georgia, Oconee River, Wallace Dam.

Wallace Dam is a pumped storage hydroelec- project on the Oconee River near Eatonton, gia. The main body of the Wallace Dam sts of a concrete gravity non-overflow sec- a gated spillway section, and east and west fill embankment sections. Transient seepage rns in the west dike station 58+00 of Wallace were studied through a saturated-unsaturated ge analysis using a finite element solution nique. Numerical results obtained from the el using Design Data III soil types compare ably with the recorded field observations. internal drainage structure is efficient in re- g pore pressures in downstream sections of arth dam. Considerable care should be given e design of the inner filter zone to avoid al piping or blockage, or both, of the filter ture due to piping. The numerical results pre- igher permeabilities in the clay fill zone with her quantity of seepage. Suitability of the element analysis is once again demonstrated alyzing transient behavior of an earth dam saturated-unsaturated flow analysis. (Moore-

UFACTURE AND USE OF ASBESTOS ENT PIPES,
Taunton.
istry and Industry, No. 17, p 667-670, 5 Sep- er, 1983. 5 Fig, 2 Tab.

riptors: *Pipes, *Asbestos cement, Cement, stos, Drinking water, Public health, Coatings, sion.

stos cement (AC) ranks as one of the major materials in service today. Estimates suggest 15 to 20% of all water distribution mains in United Kingdom are made of AC. The high ty compaction of the cement, reinforced by sbestos fiber, gives the pipe material its high gth characteristics and its inherent resistance ggressive attack. Particular features of the facturing process ensure that the asbestos are oriented such that mechanical strength in the axial and circumferential plane is devel- each lamination is consolidated in turn, as up proceeds, by a hydraulically loaded roller ; the resulting material is homogeneous, tough asily machineable; and the mandrel confers a th finish to the pipe bore. Asbestos fiber is ively inert to all substances commonly found ound water, potable water and sewage. The density compaction of the cement in the pipe provides good resistance to aggressive attacks. al studies on the effects of possibly ingested tos have indicated no increased risk arising fiber ingestion. Epidemiological studies show bstantive evidence of risk. (Baker-IVI)

POLYETHYLENE PIPING SYSTEMS FOR USE IN THE WATER INDUSTRY,
Stewarts and Lloyds Plastics, Huntingdon (England).
J. A. Denning.
Chemistry and Industry, No. 17, p 671-673, 5 September, 1983. 3 Fig, 1 Tab.

Descriptors: *Pipes, *Polyethlyene, Pipelines, Water distribution, Corrosion.

Polyethylene piping systems now being introduced to the water industry are modelled on the system used since about 1969 for the distribution of natural gas. The water system will differ in operating pressure and in the pigmentation of the polymer, but it will use the same high performance medium density polyethylene as supplied to meet gas specifications. Polyethylene piping systems do not need internal or external protection against corrosion and no environment effects should be observed on the system during its life. However, piping installed in ground contaminated with organic solvents or fuel oil can result in the water being contaminated by these pollutants diffusing through the pipe wall. (Baker-IVI)

8G. Materials

RECENT DEVELOPMENTS IN MATERIALS USED IN THE WATER SUPPLY INDUSTRY,
R. F. Stokes.
Chemistry and Industry, No. 17, p 659-663, 5 September, 1983. 7 Fig, 8 Ref.

Descriptors: *Pipes, *Water distribution, Water supply, Pipelines, Asbestos, Cement, Iron, Plastics.

Most pipes used in the drinking water systems are grey iron, either vertically cast or centrifugally spun cast, and consequently brittle. Iron pipes seldom fail in service due to strength limitations alone. Corrosion is more usually the cause and a reduction in wall thickness might be expected to exacerbate this problem. The typical method of protecting pipes from external corrosion has been to use a bitumen dip or coal tar. Currently recommended methods include the use of polyethylene sleeving as this has been shown to provide long term benefit at a relatively low cost. Zinc spray coating applied to the iron pipe before bitumen application has also been effective. Asbestos cement pipes have been used successfully for many years as pressure pipes. They are reasonably cheap and relatively trouble free in hard water areas. Plastic pipes came into use in 1955, but not until the 1960s with the use of uPVC, did their presence become significant. (Baker-IVI)
W84-02017

DEVELOPMENT OF PROTECTION SYSTEMS FOR BURIED DUCTILE IRON PIPES,
Stanton and Staveley Ltd., Nottingham (England).
H. H. Collins.
Chemistry and Industry, No. 17, p 663-666, 5 September, 1983. 1 Fig, 4 Tab, 9 Ref.

Descriptors: *Pipes, *Corrosion, Zinc, Plastic, Coatings, Tar, Ductile iron pipes, Pipelines, Water distribution, Sewer systems, United Kingdom.

The behavior of grey cast iron, when buried in a wide variety of soils, has been extensively explored by the National Bureau of Standards. Such pipe is by far the most common type used at present in Britain's cities and countryside for the transport of water, sewage, or gas. In general, the wettest soils with the lowest electrical resistivities are the most aggressive; the rate of corrosion penetration into iron tends to decrease with time; iron surfaces are attacked non-uniformly, leading to irregular pitting rather than uniform thinning; and corrosion results are extremely variable, even for identical materials buried in the same soil. For many years the standard protection to cast iron pipes has been a 70-100 micrometer coating of coal tar, applied by dipping the pipe into a bath of molten tar. Additional protection is needed by all iron pipes likely to be exposed in corrosive soils. The most convenient and economic system and widely used in the United Kingdom is encasing the pipe in a sleeve of polyethylene film 200 micrometers thick. A thin coating of metallic zinc with a top coating of coal tar or bitumen paint can be used to protect spun iron pipes. (Baker-IVI)
W84-02018

FACTORS INFLUENCING THE CHOICE OF MATERIALS FOR EPOXY RESIN RENOVATION OF WATER MAINS,
WRC Engineering, Swindon (England).
I. C. Warren.
Chemistry and Industry, No. 17, p 673-678, 5 September, 1983. 5 Fig, 5 Tab, 13 Ref.

Descriptors: *Pipes, *Water distribution, *Epoxy resins, Resins, Water mains, Microorganisms, United Kingdom.

The overall condition of the water distribution network is of concern in the water industry of the United Kingdom. Accelerated durability testing of epoxy resin linings has shown that a life of at least 20 years can be realized. No mechanism for deterioration has been observed and service lives in excess of this figure are expected. Epoxy resin linings which have been in service for up to four years are showing no signs of deterioration. Increases in microbiological activity following renovation of water mains with epoxy resin materials have frequently been noted. This activity is generally restricted to nonpathogenic microorganisms capable of growing at 22 degrees C on yeast extract agar. Epoxy resins containing benzyl alcohol can support the growth of microorganisms within the limits of the test procedure. The use of resins free of benzyl alcohol has not completely eradicated the incidence of microbial activity but it has reduced the duration of the problem. (Baker-IVI)

Desalination Plant Program to Solve Shortag of Water in the Southern Italian Islands (Sicily
W84-02090

Thermal Desalination of Sea Water in Thin Fil Plants,
W84-02092

Desalination Plant Control with Microprocesso Based Digital Technology,
W84-02094

Evaluation of Thermal Desalination Plan Water Chemistry,
W84-02104

DESIGN CRITERIA
Design of In-Line Jet Injection Blenders,
W84-01800

Optimum Design of Small Reservoirs (Tanks
W84-01881

DESORPTION
Extent of Reversibility of Polychlorinated Biphenyl Adsorption,
W84-01901 5B

DESULFATION
Desulphation New Applications: Doha East(Kuwait) and Gela (Italy) Desalination Plants,
W84-02105 3A

DETENTION TIME
Investigations on the Detention Spectrum of River Impoundments Using Naturally Provided Tracers (Ermittlung des Verweilzeitverhaltens eines Flubstausees Mittels Naturlicher, Systemeigener Tracer),
W84-02064 5B

DEVELOPING COUNTRIES
Pricing Irrigation Water in Developing Countries,
W84-01953 6C

DIFFUSIVITY
Soil Water Diffusivity Near Saturation,
W84-01864 2G

DIGITAL COMPUTERS
Desalination Plant Control with Microprocessor Based Digital Technology,
W84-02094 3A

DIPOLE DISTRIBUTION
Modelling of Discontinuities Through Dipole Distribution,
W84-01997 8B

DISCONTINUITIES
Modelling of Discontinuities Through Dipole Distribution,
W84-01997 8B

DISINFECTANTS
Reverse Osmosis Membrane Sensitivity to Ozone and Halogen Disinfectants,
W84-02097 3A

DISINFECTION
Removal of Bacteria from Water by Adhesion to Cross-Linked Poly(Vinylpyridinium Halide),
W84-02052 5F

Inactivation of Hepatitis A Virus and Indicator Organisms in Water by Free Chlorine Residuals,
W84-02059 5F

DISPERSION
Theoretical Explanation of Solute Dispersion in Saturated Porous Media at the Darcy Scale,
W84-01887 2F

DISPOSAL WELLS
Protecting Water Supply Aquifers in Areas Using Deep-well Wastewater Disposal,
W84-01790 5G

DISSOLVED GASES
Computation and Reporting of Dissolved Gas Levels,
W84-01900 5G

DISSOLVED OXYGEN
Analysis of Dissolved Oxygen Concentrations in Tail Waters of Hydroelectric Dams and the Implications for Small-Scale Hydropower Development,
W84-01896 6G

Computation and Reporting of Dissolved Gas Levels,
W84-01900 5G

Effect of an Industrial Ammonia Discharge on the Dissolved Oxygen Regime of the Willamette River, Oregon,
W84-01906 5C

Onondaga Lake and Dissolved Oxygen in Seneca River,
W84-01957 5C

Sensitivity of an Oligotrophic Lake Planktonic Bacterial Community to Oxygen-Stress,
W84-02057 2H

Influence of Dissolved Oxygen Levels on Acute Toxicity of Phenolic Compounds to Fresh Water Telecost, Notopterus notopterus (Pallas),
W84-02117 5C

DISTILLATION
Investigation of Water Desalination by Distillation Technique,
W84-02093 3A

Prevention of Calcium Sulfate Scale Deposition by a Fluidized Bed,
W84-02100 3A

Assessment of Different Scale Control Methods,
W84-02103 3A

DIVERSION
Changes in the Sedimentary Fluxes in Lake Walchensee by Anthropogenically Caused Alterations of its Catchment Area (Veranderungen im Sedimentationsgeschehen des Walchensees durch anthropogene Eingriffe in das Einzugsgebiet),
W84-02062 6G

DOMESTIC WASTE
Anaerobic Treatment of Raw Domestic Sewage at Ambient Temperatures Using a Granular Bed UASB Reactor,
W84-01817 5D

DOMESTIC WASTES
Long-Chain Alkybenzenes as Molecular Tracers of Domestic Wastes in the Marine Environment,
W84-01780 5A

DOMESTIC WATER
Reducing Water Demand and Wastewater Flow,
W84-01796 3D

DRAG
Turbulence Structure of Dilute Drag-Reducing Polymer Solutions in a Rectangular Open Channel Flow,
W84-02001 8B

DRAINAGE
In-Situ Determination of Soil Hydraulic Properties during Drainage,
W84-01862 2F

DRAWDOWN
Mathematical Model for Regional Land Subsidence Due to Pumping; 3. Integrated Equations for a Phreatic Aquifer,
W84-01883 2F

DRINKING WATER
Action of Chlorine Dioxide on Aquatic Organic Materials during the Disinfection of Drinking Water,
W84-01858 5F

Control Options for Nitrates and Fluorides,
W84-01915 5F

DROUGHT
Sub-Saharan Rainfall in the Years 1976-80: Evidence of Continued Drought,
W84-02041 2B

DROUGHTS
Impact of Droughts and Floods on the Environment,
W84-01968 4A

DRUGS
Trace Determination of the Antihistamines Tripelennamine Hydrochloride, Thenyldiamine Hydrochloride, and Chlorothen Citrate in Admixture in Animal Feed, Human Urine, and Wastewater by High-Pressure Liquid Chromatography and Use of a Fluorescence Detector,
W84-02002 5A

DRY FARMING
Measuring the Contribution of Land and Water to Agriculture,
W84-01947 8D

DYE INDUSTRY WASTES
Reverse Osmosis Treatment and Reuse of Textile Dyehouse Effluents,
W84-02111 5D

DYES
Effect of Membrane Materials and Average Pore Sizes on Reverse Osmosis Separation of Dyes,
W84-02009 5D

DYSTROPHIC LAKES
Interpretation of Phosphorus Loadings in Dystrophic Lakes,
W84-01849 2H

EARTH DAMS
Geophysical Method of Evaluating Existing Earth Embankments,
W84-01814 8D

Erosion in Relation to Filter Design Criteria in Earth Dams,
W84-01958 8D

Stress and Seepage Analysis of Earth Dams,
W84-01959 8D

EARTHWORKS
Stress and Seepage Analysis of Earth Dams,
W84-01959 8D

Unsteady Seepage Analysis of Wallace Dam,
W84-01960 8D

ECONOMIC IMPACT
Ex Post Facto Analysis of the Regional Economic Impact of Expenditures for Reservoir Recreation,
W84-01829 6G

ECOSYSTEMS
Energy Flow, Trophic Evolution and Ecosystem Management of a Kashmir Himalayan Lake,
W84-01847 2H

EDDY DIFFUSION
Comparison of the Formulation for Eddy Diffusion in Two One-Dimensional Stratification Models,
W84-01995 2H

ELECTROCHEMISTRY
Simple Method for Determining the Catalase Activity in Sludge, Sediment, and Water (Ein einfaches Verfahren zur Bestimmung der Katalase-Aktivitat in Schlammm, Sediment und Wasser),
W84-02073 5A

ELECTRODEPOSITION
Determination of Mercury in Water by Electro-Deposition and Low-Pressure Ring-Discharge Emission Spectroscopy,
W84-02005 5A

ELECTRODIALYSIS
Design and Field Trials of a 200 cu m/day Sea Water Desalination by Electrodialysis,
W84-02085 3A

Adsorption - Desorption Stack for Cyclic Electrodialysis in Open System,
W84-02086 3A

Synthesis of Ion-Exchange Membranes for Electrodialytic Treatment of Industrial Effluents,
W84-02088 5D

ELUTION
Numerical Examination of the Elution of Aquatic Sediments (Rechnerische Behandlung der Elution von Sedimenten),
W84-02068 2K

EMBANKMENTS
Unsteady Seepage Analysis of Wallace Dam,
W84-01960 8D

ENDOTOXINS
Utility of Endotoxins as a Surrogate Indicator in Potable Water Microbiology,
W84-01898 5A

ENRICHMENT
Continuous Ammonium Enrichment of a Woodland Stream: Uptake Kinetics, Leaf Decomposition, and Nitrification,
W84-01833 2H

ENTERIC BACTERIA
Phosphorus and Bacteria Elimination in a Sewage Treatment Plant with a Fourth Purification Stage (Weitestgehende Phosphor- und Bakterienentfernung in einer Klaranlage mit IV. Reiningungsstufe),
W84-02075 5D

ENTERIC VIRUSES
Method for Recovery of Enteric Viruses from Estuarine Sediments with Chaotropic Agents,
W84-02056 5A

ENVIROMENTAL EFFECTS
New Course for the Nile,
W84-02010 6G

ENVIRONMENTAL EFFECTS
Effects of Regulation of the River Tees upon Fish Populations below Cow Green Reservoir,
W84-01837 2H

Fish of Channelized and Unchannelized Sections of the Bunyip River, Victoria,
W84-01839 2H

Effects of Impoundments on Downstream Bed Materials of Two Upland Rivers in Mid-Wales and Some Ecological Implications of Such Effects,
W84-01843 6G

Acid Depositions and the Environment,
W84-01969 5G

Can We Save the Chesapeake Bay,
W84-02012 5C

Methods and Results Obtained from the Toxicological and Ecological Tests of Water Treatment Chemicals (Methoden und Ergebnisse bei der toxikologischen und okologischen Prufung von Wasserbehandlungsmitteln),
W84-02061 5F

Changes in the Sedimentary Fluxes in Lake Walchensee by Anthropogenically Caused Alterations of its Catchment Area (Veranderungen im Sedimentationsgeschehen des Walchensees durch anthropogene Eingriffe in das Einzugsgebiet),
W84-02062 6G

ENVIRONMENTAL IMPACT STATEMENT
Meet Environmental Needs for Refinery Expansions,
W84-02015 5G

ENVIRONMENTAL TRACERS
Long-Chain Alkybenzenes as Molecular Tracers of Domestic Wastes in the Marine Environment,
W84-01780 5A

EPOXY RESINS
Factors Influencing the Choice of Materials for Epoxy Resin Renovation of Water Mains,
W84-02021 8G

ERODIBILITY
Relative Erodibility of 20 California Range and Forest Soils,
W84-01867 2J

EROSION
Erosion in Relation to Filter Design Criteria in Earth Dams,
W84-01958 8D

EROSION CONTROL
Buried Pipe System for Controlling Erosion and Sediment Loss on Irrigated Land,
W84-01866 5G

Soil Erosion Awareness and Use of Conservation Tillage for Water Quality Control,
W84-01931 5G

ERROR ANALYSIS
A Method for the Reduction of Lake Model Prediction Error,
W84-01903 2H

ESTUARIES
Can We Save the Chesapeake Bay,
W84-02012 5C

ESTUARINE SEDIMENTS
Method for Recovery of Enteric Viruses from Estuarine Sediments with Chaotropic Agents,
W84-02056 5A

EUTROPHIC LAKES
Hypolimnetic Aeration of a Naturally Eutrophic Lake: Physical and Chemical Effects,
W84-01978 5G

EUTROPHICATION
Early Eutrophication in the Lower Great Lakes: New Evidence from Biogenic Silica in Sediments,
W84-01840 2H

Assessing Aquatic Productivity in the Housatonic River Using the Algal Assay: Bottle Test,
W84-01910 5C

EVALUATION
Evaluation of Operational Cloud Seeding Projects,
W84-01940 3B

EVAPORATION
Free and Forced Convection Effect on Evaporation,
W84-01967 2D

EVAPORATION PONDS
Waste Concentration vs Evaporation Ponds for Reverse Osmosis Reject Water - A Case Study,
W84-02022 5E

EXCHANGEABLE SODIUM
Effect of Exchangeable Sodium and Gypsum on Surface Runoff from Loess Soil,
W84-01876 3F

EXERGENETIC EFFICIENCY
Exergetic Efficiency of MSF Process and the Conditions of Desalination by Waste Heat,
W84-02023 3A

FALLOW
Soil Water Change as Related to Position of Wheat Straw Mulch on the Soil Surface,
W84-01873 3F

FARMING
Soil Erosion Awareness and Use of Conservation Tillage for Water Quality Control,
W84-01931 5G

FATE OF POLLUTANTS
Dynamic Bacterial Model for a Recreational Lake,
W84-01943 5B

FATHEAD MINNOWS
Structure-Toxicity Relationships for the Fathead Minnow, Pimephales promelas: Narcotic Industrial Chemicals,
W84-01975 5C

FAUNA
Attempted Reconstruction of the Fauna of Large Rivers and Flood Plains of Europe (Versuch einer Rekonstruktion der Fauna europaischer Strome und ihrer Auen),
W84-01846 6G

FERTILIZERS
Transport of Phosphorus in Surface Runoff as Influenced by Liquid and Solid Fertilizer Phosphate Addition,
W84-02121 5B

FILTERS
Scanning Electron Microscopy (SEM) Examination of Manganese Deposits on Filter Materials Used in Drinking Water Plants (Rasterelektronenmikroskopische (REM) Untersuchung von Manganablagerungen auf Filtermaterialien der Trinkwasseraufbereitung),
W84-02070 5F

FILTRATION
Optimizing Large-Scale Water Treatment Plants for Asbestos-Fiber Removal,
W84-01801 5D

Membrane Filtration for the Reuse of City Waste Water,
W84-02109 5D

FINANCING
Distributional Issues in Western Municipal and Industrial Water Supply,
W84-01950 6C

FISH
Accumulation of Mercury in Fish and Man from Reservoirs in Northern Finland,
W84-02118 5B

FISH LAKES
Restoration of Norwegian Lakes by Reduction in Sulphur Deposition,
W84-01841 5C

FISH POPULATION
Fish of Channelized and Unchannelized Sections of the Bunyip River, Victoria,
W84-01839 2H

FISH POPULATIONS
Effects of Regulation of the River Tees upon Fish Populations below Cow Green Reservoir,
W84-01837 2H

Fish Communities Along Environmental Gradients in a System of Tropical Streams,
W84-01842 2H

FLOATING DESALINATION PLANTS
Floating Desalination Plants; An Engineering, Operating and Economic Appraisal,
W84-02033 3A

FLOCCULATION
Investigations about the Influence of Small NTA-Concentrations on the Flocculation Process (Untersuchungen uber den Einfluss kleiner NTA-Konzentrationen auf den Flockungsprozess),
W84-02063 5F

LIBRARY U. OF I. URBANA-CHAMPAIGN

FLOOD PEAK
Reliability of the Design Storm Concept in Evaluating Runoff Peak Flow,
W84-01935 2E

FLOOD PLAINS
Attempted Reconstruction of the Fauna of Large Rivers and Flood Plains of Europe (Versuch einer Rekonstruktion der Fauna europaischer Strome und ihrer Auen),
W84-01846 6G

Flood Plain and Main Channel Flow Interaction,
W84-01966 8B

FLOODS
Impact of Droughts and Floods on the Environment,
W84-01968 4A

Floods: Australia's Awful Visitations,
W84-01998 2E

FLOW
Meltwater Movement in a Deep Snowpack; 1. Field Observations,
W84-01890 2C

Meltwater Movement in a Deep Snowpack; 2. Simulation Model,
W84-01891 2C

Modelling of Discontinuities Through Dipole Distribution,
W84-01997 8B

FLOW DEPTH
Flow Depth in Sand-Bed Channels,
W84-01963 8B

FLOW-INJECTION ANALYSIS
Determination of Trace Amounts of Phosphate in River Water by Flow-Injection Analysis,
W84-02003 5A

FLOW VELOCITY
Main Flow Velocity in Short River Bends,
W84-01964 8B

FLUID MECHANICS
Flow in Alluvial-River Curves,
W84-01851 2E

FLUIDIZED BEDS
Prevention of Calcium Sulfate Scale Deposition by a Fluidized Bed,
W84-02100 3A

FLUORIDE
Common Composition Characteristics of Fluoride Bearing Groundwaters,
W84-02124 2F

FLUORIDES
Control Options for Nitrates and Fluorides,
W84-01915 5F

FOOD PROCESSING INDUSTRY
Water Re-use in Processing of Pacific Shrimp,
W84-02048 3E

FOREGONE COSTS
Nature of Long Run Cost Savings Due to Water Conservation,
W84-01936 6B

FOREST MANAGEMENT
Potential for Water Yield Augmentation from Forest Management in the Eastern United States,
W84-01920 3B

Potential for Water Yield Augmentation from Forest Management in the Rocky Mountain Region,
W84-01921 3B

Potential for Augmenting Water Yield Through Forest Practices in Western Washington and Western Oregon,
W84-01923 3B

Potential for Increasing Streamflow from Sierra Nevada Watersheds,
W84-01924 3B

Watershed Management for Joint Production of Water and Timber: A Provisional Assessment,
W84-01925 3B

Water Yield Augmentation Through Forest and Range Management - Issues for the Future,
W84-01926 3B

FORESTS
Fish Communities Along Environmental Gradients in a System of Tropical Streams,
W84-01842 2H

Water Budget of an Eastern Deciduous Forest Stand,
W84-01871 2I

Throughfall and Stemflow in the Forest Nutrient Cycle,
W84-01987 2A

FRACTURES
Steady State Fluid Response in Fractured Rock: A Boundary Element Solution for a Coupled, Discrete Fracture Continuum Model,
W84-01889 2F

FREEZING
Effect of the 1981/82 Winter on Water Supplies,
W84-01991 5F

FREQUENCY
Large Falls of Rain in Wales - a Simple Statistical Case Study,
W84-01988 2B

FRICTION
Flow Depth in Sand-Bed Channels,
W84-01963 8B

FUELS
Desalinated Water Production at LNG-Terminals,
W84-02096 3A

FURROW IRRIGATION
Buried Pipe System for Controlling Erosion and Sediment Loss on Irrigated Land,
W84-01866 5G

GAS CHROMATOGRAPHY
Formation of the Bromine-Containing Trihalomethane in Water, Its Prevention and Possibility of Elimination; Part I: Determination of Bromide and Iodide in Low Concentration (Bildung bromhaltiger Trihalomethane im Wasser, ihre Verhinderung und Moglichkeiten der Elimination; I. Mitt: Bestimmung von Bromid und Iodid in Spurenkonzentrationen),
W84-02065 5A

GAS TRACERS
Stream Waste Assimilative Capacity Analysis Using Reaeration Coefficients Measured by Tracer Techniques,
W84-01929 5B

GAS WELLS
Waterflooding Will Benefit Some Gas Reservoirs,
W84-02050 3C

GEOCHEMISTRY
Development of Reaction Models for Ground-Water Systems,
W84-01984 2F

Hydrogeochemistry of Lake Turkana, Kenya: Mass Balance and Mineral Reactions in an Alkaline Lake,
W84-01985 2H

Alteration of Oceanic Crust and Geologic Cycling of Chlorine and Water,
W84-01986 2A

GEOHYDROLOGY
Alteration of Oceanic Crust and Geologic Cycling of Chlorine and Water,
W84-01986 2A

GEOLOGIC FRACTURES
Finite Element Techniques for Modeling Groundwater Flow in Fractured Aquifers,
W84-01895 2F

GEORGIA
Groundwater Laws: Opportunities for Management and Protection,
W84-01789 4B

GEOTHERMAL STUDIES
Laboratory Investigations of Steam Flow in a Porous Medium,
W84-01886 2F

GRAVITY FILTERS
Power of Gravity Cuts Water Costs,
W84-01912 5F

GRAZING
Hydrology and Soil Loss from a High-Fertility, Rotational Pasture Program,
W84-01807 4C

Nitrogen Loss from a High-Fertility, Rotational Pasture Program,
W84-01808 5B

GROUND RADAR
Water Centre Develops Ground Radar,
W84-02013 7B

GROUNDWATER
Determination of Bulk Rock Properties from Ground-water Level Fluctuations,
W84-01813 2F

Development of Reaction Models for Ground-Water Systems,
W84-01984 2F

Common Composition Characteristics of Fluoride Bearing Groundwaters,
W84-02124 2F

GROUNDWATER MANAGEMENT
Groundwater Laws: Opportunities for Management and Protection,
W84-01789 4B

GROUNDWATER MOVEMENT
Steady State Fluid Response in Fractured Rock: A Boundary Element Solution for a Coupled, Discrete Fracture Continuum Model,
W84-01889 2F

Finite Element Techniques for Modeling Groundwater Flow in Fractured Aquifers,
W84-01895 2F

Modeling Ground-Water Flow at Love Canal, New York,
W84-01956 5B

GROUNDWATER POLLUTION
Restoration of Aquifers,
W84-01775 5G

Behavior of Organic Compounds during Infiltration of River Water to Groundwater. Field Studies,
W84-01776 5B

Movement of Typhoid Organisms in Saturated Permeable Soil,
W84-01787 5B

Tetrachloroethylene Contamination of Groundwater in Kalamazoo,
W84-01788 5F

Contaminated Groundwater Treatability - A Case Study,
W84-01791 5F

Chemistry of Reduced Sulfur Species and Their Removal from Groundwater Supplies,
W84-01792 5F

Soda Ash Treatment of a Strontium-90-Contaminated Groundwater Seep,
W84-01810 5G

GROUNDWATER RECHARGE
Behavior of Organic Compounds during Infiltration of River Water to Groundwater. Field Studies,
W84-01776 5B

Leaky Acres Recharge Facility: A Ten-Year Evaluation,
W84-01928 4B

GULLS
Contamination of a Major Water Supply by Gulls (Larus sp.); A Study of the Problem and Remedial Action Taken,
W84-01897 5C

GYPSUM
Effect of Exchangeable Sodium and Gypsum on Surface Runoff from Loess Soil,
W84-01876 3F

HAZARDOUS MATERIALS
Effects of Toxic Pollutants on Indicator Germs in Large-Scale Solid-Waste Ecosystems,
W84-01826 5A

HEAT EXCHANGERS
Seawater Desalination with Very Low Energy Consumption,
W84-02028 3A

HEAVY METALS
Sewage Sludge for Cultivating Freshwater Algae and the Fate of Heavy Metals at Higher Trophic Organisms; I. Different Methods of Extracting Sewage Sludge on the Properties of Sludge Extracts,
W84-01845 5E

HEPATITIS A VIRUS
Inactivation of Hepatitis A Virus and Indicator Organisms in Water by Free Chlorine Residuals,
W84-02059 5F

HERBICIDES
Herbicide Runoff from Experimental Watersheds,
W84-01806 5B

Loss of Fall-Applied 2,4-D in Spring Runoff from a Small Agricultural Watershed,
W84-01812 5B

HORIZONTAL DISPLACEMENT
Mathematical Model for Regional Land Subsidence Due to Pumping; 3. Integrated Equations for a Phreatic Aquifer,
W84-01883 2F

HOUSATONIC RIVER
Assessing Aquatic Productivity in the Housatonic River Using the Algal Assay: Bottle Test,
W84-01910 5C

HYDRAULIC EQUIPMENT
Pumps that Play Turbines,
W84-01914 8C

Modeling Tells the Hydraulic Story,
W84-01916 6A

HYDROCARBONS
Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments - V; Organic Carbons and Hydrocarbons in Sediments,
W84-01899 5A

HYDRODYNAMICS
Stability Analysis of Water Movement in Unsaturated Porous Materials 2. Numerical Studies,
W84-01893 2F

HYDROELECTRIC POWER
Analysis of Dissolved Oxygen Concentrations in Tail Waters of Hydroelectric Dams and the Implications for Small-Scale Hydropower Development,
W84-01896 6G

HYDROGEN ION CONCENTRATION
Effect of Acidification, Metals and Metalloids on Sediment Microorganisms,
W84-01904 5C

Effects of Changes in pH on Transparency and Thermal Regimes of Lohi Lake, near Sudbury, Ontario,
W84-01974 2H

Regulation of the pH Value in Aquaculture, Taking the NH4(+)/NH3(-) Ratio into Account, (Steuerung des pH-Wertes in der Aquakultur unter Berucksichtigung des NH4(+)/NH3(-)Verhaltnisses),
W84-02074 5G

HYDROGEN SULFIDE
Chemistry of Reduced Sulfur Species and Their Removal from Groundwater Supplies,
W84-01792 5F

HYDROLOGY
Statistical Estimation of Polynomial Generalized Covariance Functions and Hydrologic Applications,
W84-01884 2A

HYPOLIMNION
Hypolimnetic Aeration of a Naturally Eutrophic Lake: Physical and Chemical Effects,
W84-01978 5G

IMPOUNDMENTS
Nutrient Retention and Transformation in Relation to Hydraulic Flushing Rate in a Small Impoundment,
W84-01831 2H

Effects of Impoundments on Downstream Bed Materials of Two Upland Rivers in Mid-Wales and Some Ecological Implications of Such Effects,
W84-01843 6G

INDIA
Problems of Water Resources Planning in India,
W84-01942 6A

Relationship Between Eastern Equatorial Pacific Sea Surface Temperatures and Rainfall over India and Sri Lanka,
W84-02044 2B

Physical Basis for Changes in the Phases of the Summer Monsoon over India,
W84-02046 2B

INDICATORS
Utility of Endotoxins as a Surrogate Indicator in Potable Water Microbiology,
W84-01898 5A

In Situ Peristence of Indicator Bacteria in Streams Polluted with Acid Mine Drainage,
W84-01911 5A

INDUSTRIAL WASTES
Polychlorinated Biphenyl Pollution from Shipbuilding in Nagasaki Bay, Japan,
W84-01828 5B

Wastewater Treatment - An Award-Winning System,
W84-02014 5D

Meet Environmental Needs for Refinery Expansions,
W84-02015 5G

INDUSTRIAL WASTEWATER
Anaerobic Biotechnology for Industrial Wastewater Treatment,
W84-01778 5D

INDUSTRIAL WATER
Distributional Issues in Western Municipal and Industrial Water Supply,
W84-01950 6C

Improve Plant Water Quality,
W84-02016 5D

INFILTRATION
Behavior of Organic Compounds during Infiltration of River Water to Groundwater. Field Studies,
W84-01776 5B

Mathematical Simulation of Interdependent Surface and Subsurface Hydrologic Processes,
W84-01892 2A

Experts Discuss Private Sector Infiltration/Inflow.
W84-01918 5D

Dynamic Model for the Overland Flow on an Infiltrating Catchment,
W84-01994 2E

INJECTION WELLS
Aquifer Thermal Energy Storage. An Attempt to Counter Free Thermal Convection,
W84-01885 4B

IODIDE
Formation of the Bromine-Containing Trihalomethane in Water, Its Prevention and Possibility of Elimination; Part I: Determination of Bromide and Iodide in Low Concentration (Bildung bromhaltiger Trihalomethane im Wasser, ihre Verhinderung und Moglichkeiten der Elimination; I. Mitt: Bestimmung von Bromid und Iodid in Spurenkonzentrationen),
W84-02065 5A

ION CHROMATOGRAPHY
Determination of Chloride, Nitrate, Sulphate and Total Sulphur in Environmental Samples by Single-Column Ion Chromatography,
W84-02007 5A

ION EXCHANGE
Characteristics of Flow and Mass Transfer Rate in an Electrodialyzer Compartment Including Spacer,
W84-02087 3A

Synthesis of Ion-Exchange Membranes for Electrodialytic Treatment of Industrial Effluents,
W84-02088 5D

IRRIGATION
Mathematical Model for Border Strip Irrigation,
W84-01894 3F

Estimation of Direct Irrigation Benefits,
W84-01933 6B

Pricing Irrigation Water in Developing Countries,
W84-01953 6C

LIBRARY U. OF I. URBANA-CHAMPAIGN

RIGATION CANALS
Inexpensive Technique to Measure Subsidence Along Canals,
W84-01816 8D

RIGATION EFFECTS
Measuring the Contribution of Land and Water to Agriculture,
W84-01947 8D

RIGATION WATER
Distributional Issues in Western Municipal and Industrial Water Supply,
W84-01950 6C

OOTENAY LAKE
Primary Productivity in a Large, Temperate Lake with River Interflow: Kootenay Lake, British Columbia,
W84-01972 2H

RAFT MILLS
Chlorinated Neutral Organics in Biologically Treated Bleached Kraft Mill Effluents,
W84-01781 5A

GUNA DE BAY
Water Quality Management of Laguna de Bay,
W84-01955 5G

KE ACIDIFICATION
Zinc, Manganese, and Strontium in Opercula and Scales of Brook Trout (Salvelinus fontinalis) as Indicators of Lake Acidification,
W84-01980 5C

KE MICHIGAN
From Dream to Reality: Lake Michigan Water for Four Chicago Suburbs,
W84-01786 5F

KE SEDIMENTS
Extent of Reversibility of Polychlorinated Biphenyl Adsorption,
W84-01901 5B

Effect of Acidification, Metals and Metalloids on Sediment Microorganisms,
W84-01904 5C

Anthropogenic Zinc and Cadmium Burdens in Sediments of Selected Southern Ontario Lakes,
W84-01973 5B

KE TURKANA
Hydrogeochemistry of Lake Turkana, Kenya: Mass Balance and Mineral Reactions in an Alkaline Lake,
W84-01985 2H

KES
Landsat Imagery for Assessing Changes in Lake Areas at Dungeness, on the Kent Coast,
W84-01818 2H

Phosphorus and Calcium Carbonate Solubilities in Lake Kinneret,
W84-01836 2H

Early Eutrophication in the Lower Great Lakes: New Evidence from Biogenic Silica in Sediments,
W84-01840 2H

Energy Flow, Trophic Evolution and Ecosystem Management of a Kashmir Himalayan Lake,
W84-01847 2H

Modeling Inland Water Quality Using Landsat Data,
W84-01853 5G

A Method for the Reduction of Lake Model Prediction Error,
W84-01903 2H

Onondaga Lake and Dissolved Oxygen in Seneca River,
W84-01957 5C

Orthophosphate Turnover Time in Shallow Productive Lakes,
W84-01979 2H

Examination of Bioaccumulation and Biomagnification of Metals in a Precambrian Shield Lake,
W84-02119 5B

Macrobenthos of Lake Naini Tal (U.P., India) with Particular Reference to Pollution,
W84-02123 5C

LAND DISPOSAL
Assessing the Suitability of Soils with Macropores for Subsurface Liquid Waste Disposal,
W84-01805 5D

LAND RECLAMATION
Predicting Erosion and Deposition on a Strip-mined and Reclaimed Area,
W84-01944 2J

LANDSAT
Landsat Imagery for Assessing Changes in Lake Areas at Dungeness, on the Kent Coast,
W84-01818 2H

LAS VEGAS
Water for Las Vegas Metropolitan Area,
W84-01774 6D

LEACHING
Brackish-Water Aquaculture in Pyrite-Bearing Tropical Soils,
W84-01834 2K

LEAKAGE
Water Usage and the Quantification of Unaccounted Water in a Universally Meter Supply Area,
W84-01821 3D

LEGAL ASPECTS
From Dream to Reality: Lake Michigan Water for Four Chicago Suburbs,
W84-01786 5F

Upstream-Downstream: Rights and Responsibilities,
W84-01982 6E

Priority Pollution Rights: Adapting Pollution Control to a Variable Environment,
W84-02049 6E

LIGHT
Light-Productivity Model for Onondaga Lake, N.Y.,
W84-01954 2H

LIGHT INTENSITY
Light Intensity and Relative Light Changes as Factors Regulating Stream Drift,
W84-01848 2H

LIMITING NUTRIENTS
Nutrient Limitation in Two Arctic Lakes, Alaska,
W84-01977 2H

LIQUEFIED NATURAL GAS
Desalinated Water Production at LNG-Terminals,
W84-02096 3A

LITTER
Influence of Elevated Nitrate Concentration on Rate of Leaf Decomposition in a Stream,
W84-01832 2H

Leaf Processing in Two Contrasting Beech Forest Streams: Effects of Physical and Biotic Factors on Litter Breakdown,
W84-01844 2H

LOVE CANAL
Modeling Ground-Water Flow at Love Canal, New York,
W84-01956 5B

MACROPHYTES
Trophic State Classification of Lakes with Aquatic Macrophytes,
W84-01981 2H

MACROPORES
Assessing the Suitability of Soils with Macropores for Subsurface Liquid Waste Disposal,
W84-01805 5D

MAINTENANCE
Reliability Assurance Survey - an Initial Step Towards Increased Operating Reliability at Existing Desalination Facilities,
W84-02039 3A

MANAGEMENT
Desalination Plant Program to Solve Shortage of Water in the Southern Italian Islands (Sicily),
W84-02090 3A

MANGANESE
Scanning Electron Microscopy (SEM) Examination of Manganese Deposits on Filter Materials Used in Drinking Water Plants (Rasterelektronenmikroskopische (REM) Untersuchung von Manganablagerungen auf Filtermaterialien der Trinkwasseraufbereitung),
W84-02070 5F

MARSHES
Sedimentation, Accretion, and Subsidence in Marshes of Barataria Basin, Louisiana,
W84-01835 2L

MASS BALANCE
Hydrogeochemistry of Lake Turkana, Kenya: Mass Balance and Mineral Reactions in an Alkaline Lake,
W84-01985 2H

MASSACHUSETTS
Recreation at Drinking Water Reservoirs in Massachusetts: A Survey of Water Managers,
W84-01934 6G

MATHEMATICAL MODELS
Estimation of Direct Irrigation Benefits,
W84-01933 6B

Nonlinear Runoff Modeling: Parameter Identification,
W84-01961 2E

Comparison of the Formulation for Eddy Diffusion in Two One-Dimensional Stratification Models,
W84-01995 2H

Investigations on the Detention Spectrum of River Impoundments Using Naturally Provided Tracers (Ermittlung des Verweilzeitverhaltens eines Flubstausees Mittels Naturlicher, Systemeigener Tracer),
W84-02064 5B

MAYFLIES
Light Intensity and Relative Light Changes as Factors Regulating Stream Drift,
W84-01848 2H

MEASURING INSTRUMENTS
Geophysical Method of Evaluating Existing Earth Embankments,
W84-01814 8D

Passive Microwave Sensing of Soil Moisture Content: The Effects of Soil Bulk Density and Surface Roughness,
W84-01852 2G

Survey of Radar Rain Measurement Techniques,
W84-01855 2B

MECHANICAL EQUIPMENT
Design of In-Line Jet Injection Blenders,
W84-01800 8C

MEMBRANE PROCESSES
Effect of Membrane Materials and Average Pore Sizes on Reverse Osmosis Separation of Dyes,
W84-02009 5D

Ultrafiltration Membrane Processes - The Sleeping Giant,
W84-02082 3A

Characteristics of Flow and Mass Transfer Rate in an Electrodialyzer Compartment Including Spacer,
W84-02087 3A

Fouling Studies and Mathematical Modelling of Ultrafiltration of Textile Desizing Effluents,
W84-02106 5D

Control of Biological Fouling in Seawater Reverse Osmosis Desalination,
W84-02108 3A

Application of Membrane Separation Processes to the Treatment of Industrial Effluents for Water Reuse,
W84-02110 5D

Study of Emulsified Liquid Membrane Treatment of Phenolic Waste Water,
W84-02116 5D

MEMBRANES
Experience with Desalination of Sea and Brackish Water Using Minimum Pretreatment and High Temperature,
W84-02080 3A

Polypiperazinamides: New Polymers Useful for Membrane Processes,
W84-02099 3A

Membrane Filtration for the Reuse of City Waste Water,
W84-02109 5D

MERCURY
Histological Observations in Gills of the Teleost Sarotherodon mossambicus with Reference to Mercury Toxicity,
W84-01825 5C

Determination of Mercury in Water by Electro-Deposition and Low-Pressure Ring-Discharge Emission Spectroscopy,
W84-02005 5A

Accumulation of Mercury in Fish and Man from Reservoirs in Northern Finland,
W84-02118 5B

METAL-FINISHING WASTES
Concentrations and Speciation of Lead, Zinc, and Cadmium in Seawater-like Smelter Effluent and Adjacent Marine Environments, Port Pirie, South Australia,
W84-01838 5B

METALLOIDS
Effect of Acidification, Metals and Metalloids on Sediment Microorganisms,
W84-01904 5C

METALS
Concentrations and Speciation of Lead, Zinc, and Cadmium in Seawater-like Smelter Effluent and Adjacent Marine Environments, Port Pirie, South Australia,
W84-01838 5B

Effect of Acidification, Metals and Metalloids on Sediment Microorganisms,
W84-01904 5C

Examination of Bioaccumulation and Biomagnification of Metals in a Precambrian Shield Lake,
W84-02119 5B

MICROORGANISMS
Effect of Acidification, Metals and Metalloids on Sediment Microorganisms,
W84-01904 5C

Microcosm and Experimental Pond Evaluation of Microbial Community Response to Synthetic Oil Contamination in Freshwater Sediments,
W84-02053 5C

Simple Method for Determining the Catalase Activity in Sludge, Sediment, and Water (Ein einfaches Verfahren zur Bestimmung der Katalase-Aktivitat in Schlammm, Sediment und Wasser),
W84-02073 5A

MINE DRAINAGE
Desalination of Coalmine Drainage Water by Reverse Osmosis,
W84-02115 3A

MINE WASTES
Characterizing Unsaturated Hydraulic Conductivity of Western Kentucky Surface Mine Spoils and Soils,
W84-01872 2G

Bacteria and Acidic Drainage from Coal Refuse: Inhibition by Sodium Lauryl Sulfate and Sodium Benzoate,
W84-02055 5G

MINERALS
Hydrogeochemistry of Lake Turkana, Kenya: Mass Balance and Mineral Reactions in an Alkaline Lake,
W84-01985 2H

MIXING
Transverse Mixing in Wide and Shallow River: Case Study,
W84-01773 2E

MODEL STUDIES
Resource Allocation to Interrelated Projects,
W84-01880 6A

Mathematical Model for Border Strip Irrigation,
W84-01894 3F

A Method for the Reduction of Lake Model Prediction Error,
W84-01903 2H

Modeling Tells the Hydraulic Story,
W84-01916 6A

MODEL TESTING
Modeling Inland Water Quality Using Landsat Data,
W84-01853 5G

MOISTURE AVAILABILITY
Models for Estimating In-Situ Potential Extractable Water using Soil Physical and Chemical Properties,
W84-01869 2G

MONOHALOGENATED BIPHENYLS
Degradation and Total Mineralization of Monohalogenated Biphenyls in Natural Sediment and Mixed Bacterial Culture,
W84-02060 5B

MONSOONS
Onset of the Australian Monsoon During Winter MONEX: Synoptic Aspects,
W84-02045 2B

Physical Basis for Changes in the Phases of the Summer Monsoon over India,
W84-02046 2B

MOTIVATION
Managing River Environments for the Participation Motives of Stream Floaters,
W84-01830 6B

MOUND FORMATION
Mound Formation at Culvert Outlets,
W84-01941 8B

MOUNTAINS
Hydrometeorological Significance of Rime Ice Deposits in the Colorado Rockies,
W84-01948 2C

MULCHES
Soil Water Change as Related to Position of Wheat Straw Mulch on the Soil Surface,
W84-01873 3F

MULTI-EFFECT BOILING
Comparative Study Between Vapor Compression and Multi Effect Boiling Desalination Systems,
W84-02035 3A

MULTI-EFFECT DISTILLATION
One Year of Operation of Israel Desalination Engineering's Multi-Effect Distillation U.S. Virgin Islands,
W84-02025 3A

MULTI-EFFECT PROCESS
Application of the Multi-Effect Process at High Temperature for Large Seawater Desalination Plants,
W84-02036 3A

MULTI-STAGE FLASH EVAPORATION
Operating Experience and Performance Data on an Advanced Barge-Mounted VTE/VC Seawater Desalination Plant,
W84-02032 3A

MULTICRITERIA ANALYSIS
Multicriteria Analysis of Water Allocation in a River Basin: The Tchebycheff Approach,
W84-01879 6D

MULTIPLE-EFFECT FALLING FILM EVAPORATOR
Computer Simulations of Multiple-Effect FFE-VC Systems for Water Desalination,
W84-02037 3A

MULTIPLE EFFECT PROCESS
Seawater Desalination with Very Low Energy Consumption,
W84-02028 3A

MULTISTAGE FLASH EVAPORATOR
Desalting Water Costs Using Waste Heat from Power Systems Combined with the VTFE and Vapor Compression,
W84-02027 3A

MULTIVARIATE ANALYSIS
Predicting Coliform Concentrations in Upland Impoundments: Design and Calibration of a Multivariate Model,
W84-02058 5G

MUNICIPAL WASTES
Long-Chain Alkybenzenes as Molecular Tracers of Domestic Wastes in the Marine Environment,
W84-01780 5A

MUNICIPAL WATER
Distributional Issues in Western Municipal and Industrial Water Supply,
W84-01950 6C

NATIONAL WATER ASSESSMENT
National Water Assessment: Needed or Not,
W84-01945 6A

NETWORKS
Sub-Optimal Constant-Volume Control for Open Channel Networks,
W84-01996 4A

LIBRARY U. OF I. URBANA-CHAMPAIGN

VADA
Water for Las Vegas Metropolitan Area,
W84-01774 6D

Precipitation in Southern Nevada,
W84-01965 2B

GERIA
Pollution Levels in Some Nigerian Rivers,
W84-01905 5A

TRATES
Control Options for Nitrates and Fluorides,
W84-01915 5F

Determination of Chloride, Nitrate, Sulphate nd Total Sulphur in Environmental Samples by ingle-Column Ion Chromatography,
W84-02007 5A

TRIFICATION
Effect of an Industrial Ammonia Discharge on ne Dissolved Oxygen Regime of the Willamette iver, Oregon,
W84-01906 5C

Nitrification Back on Track,
W84-01913 5D

TRILOTRIACETATE
nvestigations about the Influence of Small TA-Concentrations on the Flocculation Proc-ss (Untersuchungen uber den Einfluss kleiner TA-Konzentrationen auf den Flockungspro-ess),
W84-02063 5F

TRITES
Spectrophotometric Determination of Micro mounts of Nitrite in Water and Soil,
W84-02004 5A

TROGEN COMPOUNDS
Waste Water Combustion in a Confined Swirl lame,
W84-01993 5D

TRIENTS
Nutrient Retention and Transformation in Rela-on to Hydraulic Flushing Rate in a Small Im-oundment,
W84-01831 2H

L POLLUTION
Microcosm and Experimental Pond Evaluation f Microbial Community Response to Synthetic il Contamination in Freshwater Sediments,
W84-02053 5C

IGOTROPHIC LAKES
Effect of Atmospheric Sulfur on the Composi-on of Three Adirondack Lakes,
W84-01976 5B

EN CHANNELS
Sub-Optimal Constant-Volume Control for pen Channel Networks,
W84-01996 4A

Turbulence Structure of Dilute Drag-Reducing olymer Solutions in a Rectangular Open Chan-el Flow,
W84-02001 8B

EGON
Potential for Augmenting Water Yield Through orest Practices in Western Washington and Western Oregon,
W84-01923 3B

GANIC CARBON
Comparative Study on Organic Constituents in olluted and Unpolluted Inland Aquatic Envi-onments - V; Organic Carbons and Hydrocar-ons in Sediments,
W84-01899 5A

ORGANIC COMPOUNDS
Effect of Solids Concentration on the Sorptive Partitioning of Hydrophobic Pollutants in Aquatic Systems,
W84-01779 5B

Toxicity of Selected Priority Pollutants to Various Aquatic Organisms,
W84-01824 5C

Structure-Toxicity Relationships for the Fathead Minnow, Pimephales promelas: Narcotic Industrial Chemicals,
W84-01975 5C

ORGANIC MATTER
Influence of Elevated Nitrate Concentration on Rate of Leaf Decomposition in a Stream,
W84-01832 2H

Leaf Processing in Two Contrasting Beech Forest Streams: Effects of Physical and Biotic Factors on Litter Breakdown,
W84-01844 2H

Action of Chlorine Dioxide on Aquatic Organic Materials during the Disinfection of Drinking Water,
W84-01858 5F

ORTHOPHOSPHATE
Orthophosphate Turnover Time in Shallow Productive Lakes,
W84-01979 2H

OVERLAND FLOW
Dynamic Model for the Overland Flow on an Infiltrating Catchment,
W84-01994 2E

OXALATE
Anaerobic Oxalate Degradation: Widespread Natural Occurrence in Aquatic Sediments,
W84-02051 2H

OXIDATION
Biotechnology in the Water Industry,
W84-01878 5D

OYSTERS
Acute Toxicity of Picric Acid and Picramic Acid to Rainbow Trout Salmo gairdneri, and American Oyster, Crassostrea virginica,
W84-01951 5C

OZONE
Reaction Rates of Polynuclear Aromatic Hydrocarbons with Ozone in Water,
W84-01782 5F

PARTITION COEFFICIENTS
Effect of Solids Concentration on the Sorptive Partitioning of Hydrophobic Pollutants in Aquatic Systems,
W84-01779 5B

PASTURE MANAGEMENT
Nitrogen Loss from a High-Fertility, Rotational Pasture Program,
W84-01808 5B

PATH OF POLLUTANTS
Modeling Ground-Water Flow at Love Canal, New York,
W84-01956 5B

PENNSYLVANIA
Calibration of Snyder Coefficients for Pennsylvania,
W84-01949 2A

PERMEABILITY
Sandstone Water Sensitivity: Existence of a Critical Rate of Salinity Decrease for Particle Capture,
W84-01992 2F

PERMEABILITY COEFFICIENT
In-Situ Determination of Soil Hydraulic Properties during Drainage,
W84-01862 2F

Characterizing Unsaturated Hydraulic Conductivity of Western Kentucky Surface Mine Spoils and Soils,
W84-01872 2G

PERMITS
Alternative Structures for Water Rights Markets,
W84-01882 6D

Cost-Effective Regulatory Options for Water Quality Limited Streams,
W84-01927 5G

PESTICIDES
Analysis of Pesticides and Other Organic Pollutants by Preconcentration and Chromatographic Techniques,
W84-02120 5A

PHENOLS
Study of Emulsified Liquid Membrane Treatment of Phenolic Waste Water,
W84-02116 5D

Influence of Dissolved Oxygen Levels on Acute Toxicity of Phenolic Compounds to Fresh Water Telecost, Notopterus notopterus (Pallas),
W84-02117 5C

PHOSPHATES
Determination of Trace Amounts of Phosphate in River Water by Flow-Injection Analysis,
W84-02003 5A

PHOSPHORUS
Interpretation of Phosphorus Loadings in Dystrophic Lakes,
W84-01849 2H

Trophic State Classification of Lakes with Aquatic Macrophytes,
W84-01981 2H

Transport of Phosphorus in Surface Runoff as Influenced by Liquid and Solid Fertilizer Phosphate Addition,
W84-02121 5B

PHOSPHORUS REMOVAL
Phosphorus and Bacteria Elimination in a Sewage Treatment Plant with a Fourth Purification Stage (Weitestgehende Phosphor- und Bakterienentfernung in einer Klaranlage mit IV. Reinigungsstufe),
W84-02075 5D

PHYTOPLANKTON
Energy Flow, Trophic Evolution and Ecosystem Management of a Kashmir Himalayan Lake,
W84-01847 2H

Primary Productivity in a Large, Temperate Lake with River Interflow: Kootenay Lake, British Columbia,
W84-01972 2H

PICRAMIC ACID
Acute Toxicity of Picric Acid and Picramic Acid to Rainbow Trout Salmo gairdneri, and American Oyster, Crassostrea virginica,
W84-01951 5C

PICRIC ACID
Acute Toxicity of Picric Acid and Picramic Acid to Rainbow Trout Salmo gairdneri, and American Oyster, Crassostrea virginica,
W84-01951 5C

PIPES
Recent Developments in Materials Used in the Water Supply Industry,
W84-02017 8G

Development of Protection Systems for Buried Ductile Iron Pipes,
W84-02018 8G

Manufacture and Use of Asbestos Cement Pipes,
W84-02019 8F

Polyethylene Piping Systems for Use in the Water Industry,
W84-02020 8F

Factors Influencing the Choice of Materials for Epoxy Resin Renovation of Water Mains,
W84-02021 8G

PLANNING
Enhanced Role of Water Conservation in the Cost-Benefit Analysis of Water Projects,
W84-01930 6B

Problems of Water Resources Planning in India,
W84-01942 6A

Desired and Achieved Outcomes in Federal Water Resources Planning,
W84-01952 6A

Water Quality Management of Laguna de Bay,
W84-01955 5G

PLUMBING FIXTURES
Minimum-Flow Plumbing Fixtures,
W84-01798 3D

POLICY MAKING
Acid Rain: A Rapidly Shifting Scene,
W84-01777 5B

Choosing the Optimal Water Conservation Policy,
W84-01795 3D

POLLUTANT IDENTIFICATION
Simple Determination of Oxime Carbamates in Soil and Environmental Water by High Pressure Liquid Chromatography,
W84-01861 5A

Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments - V; Organic Carbons and Hydrocarbons in Sediments,
W84-01899 5A

Stabilized Temperature Platform Furnace with Zeeman Effect Background Correction for Trace Analysis in Wastewater,
W84-01971 5A

POLLUTANTS
Chemical Oxidizability of Organic Water Pollutants (Chemische Oxidierbarkeiten organischer Wasserinhaltsstoffe (Ergebnisbericht)),
W84-02066 5A

POLLUTION LOAD
Pollution Levels in Some Nigerian Rivers,
W84-01905 5A

POLY (VINYLPYRIDINIUM HALIDE)
Removal of Bacteria from Water by Adhesion to Cross-Linked Poly(Vinylpyridinium Halide),
W84-02052 5F

POLYCHLORINATED BIPHENYLS
PCB Partitioning in Sediment-Water Systems: The Effect of Sediment Concentration,
W84-01811 5B

Polychlorinated Biphenyl Pollution from Shipbuilding in Nagasaki Bay, Japan,
W84-01828 5B

Extent of Reversibility of Polychlorinated Biphenyl Adsorption,
W84-01901 5B

POLYCYCLIC AROMATIC HYDROCARBONS
One-dimensional Thin Layer Chromatographic Separation and Fluorometric Quantification of Polycyclic Aromatic Hydrocarbons in Water Samples (Eindimensionale dunnschichtchromatographische Trennung und fluorometrische Bestimmung von polycyclischen aromatischen Kohlenwasserstoffen aus Wasserproben),
W84-02071 5A

POLYELECTROLYTES
Improve Plant Water Quality,
W84-02016 5D

POLYETHLYENE
Polyethylene Piping Systems for Use in the Water Industry,
W84-02020 8F

POLYMERS
Turbulence Structure of Dilute Drag-Reducing Polymer Solutions in a Rectangular Open Channel Flow,
W84-02001 8B

POLYNUCLEAR AROMATIC HYDROCARBONS
Reaction Rates of Polynuclear Aromatic Hydrocarbons with Ozone in Water,
W84-01782 5F

PONDING
Calculation of Sorptivity from Constant-Rate Rainfall Infiltration Measurement,
W84-01863 2G

POPULATION DYNAMICS
Population Ecology of Rotifers as a Bioassay Tool for Ecotoxicological Tests in Aquatic Environments,
W84-01827 5A

POROUS MEDIA
Theoretical Explanation of Solute Dispersion in Saturated Porous Media at the Darcy Scale,
W84-01887 2F

POTABLE WATER
Wastewater Reuse: A Resource or a Nuisance,
W84-01799 5F

POWERPLANTS
Make-Up Water Treatment at Thermal Power Plants and Multiple Waste Water Re-Use,
W84-02112 5D

PRECIPITATION
Source Contributions to Acid Precipitation in Texas,
W84-01783 5B

Temporal Variations in Acid Precipitation over New York State-What the 1965-1979 USGS Data Reveal,
W84-01784 5B

SEAGULLS
Seagull Pollution of Reservoirs,
W84-01823 5B

SEASONAL VARIATION
Environmental Studies of Enteric Bacteria Longevity in Membrane Filter Chambers,
W84-01804 5D

SEAWATER
Seawater vs. Brackish Water Desalting: Technology, Operating Problems and Overall Economics,
W84-02024 3A

Desalination of High Salinity Sea Water by Reverse Osmosis (Summary),
W84-02083 3A

Thermal Desalination of Sea Water in Thin Film Plants,
W84-02092 3A

SEDIMENT CONTROL
Buried Pipe System for Controlling Erosion and Sediment Loss on Irrigated Land,
W84-01866 5G

SEDIMENT TRANSPORT
Characteristic Parameters of Nonequilibrium Processes in Alluvial Channels of Finite Length,
W84-01888 2J

Changes in the Sedimentary Fluxes in Lake Walchensee by Anthropogenically Caused Alterations of its Catchment Area (Veranderungen im Sedimentationsgeschehen des Walchensees durch anthropogene Eingriffe in das Einzugsgebiet),
W84-02062 6G

SEDIMENTATION
Sedimentation, Accretion, and Subsidence in Marshes of Barataria Basin, Louisiana,
W84-01835 2L

Sediment Deposition Estimation from Cesium-137 Measurements,
W84-01938 2J

SEDIMENTS
PCB Partitioning in Sediment-Water Systems: The Effect of Sediment Concentration,
W84-01811 5B

Continuous Ammonium Enrichment of a Woodland Stream: Uptake Kinetics, Leaf Decomposition, and Nitrification,
W84-01833 2H

Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments - V; Organic Carbons and Hydrocarbons in Sediments,
W84-01899

Anaerobic Oxalate Degradation: Wide Natural Occurrence in Aquatic Sediments,
W84-02051

Microcosm and Experimental Pond Eval of Microbial Community Response to Sy Oil Contamination in Freshwater Sedimen
W84-02053

Numerical Examination of the Elution of ic Sediments (Rechnerische Behandlun Elution von Sedimenten),
W84-02068

SEEPAGE
Stress and Seepage Analysis of Earth
W84-01959

Unsteady Seepage Analysis of Wallace
W84-01960

SEISMIC PROPERTIES
Geophysical Method of Evaluating E Earth Embankments,
W84-01814

SEWER SYSTEMS
Water Centre Develops Ground Radar,
W84-02013

SHALLOW WELLS
Movement of Typhoid Organisms in Sat Permeable Soil,
W84-01787

SHEET-PILES
Modelling of Discontinuities Through L Distribution,
W84-01997

SHEVCHENKO
Operating Experience of Desalination Ur Schevchenko,
W84-02038

SIERRA NEVADA
Potential for Increasing Streamflow from Nevada Watersheds,
W84-01924

SILVER SULFATE
Reduction or Substitution of Silver S Using the Standard Method for Che Oxygen Demand (Verminderung oder Sub tion von Silbersulfat bei der CSB-Stan Methode),
W84-02072

SIMULATION
Lake Temperature Dynamics in Hybrid Co System,
W84-01772

Simulation of M.S.F. Desalination Plants,
W84-02034

SLOPE
Effect of Slope on Water Balance under Ce Pivot Irrigation,
W84-01868

SLOPES
Mathematical Simulation of Interdependent face and Subsurface Hydrologic Processes,
W84-01892

SLUDGE
Comparative Study on Organic Constituen Polluted and Unpolluted Inland Aquatic E ronments - V; Organic Carbons and Hydr bons in Sediments,
W84-01899

UDGE DISPOSAL
Sewage Sludge for Cultivating Freshwater Algae and the Fate of Heavy Metals at Higher Trophic Organisms; I. Different Methods of Extracting Sewage Sludge on the Properties of Sludge Extracts,
W84-01845 5E

UDGE MANAGEMENT
ntegrated Wastewater Management,
V84-01771 5D

OW COVER
Model Study of the Short-Term Climatic and Hydrologic Effects of Sudden Snow-Cover Removal,
V84-02042 2A

OWMELT
Loss of Fall-Applied 2,4-D in Spring Runoff rom a Small Agricultural Watershed,
V84-01812 5B

Meltwater Movement in a Deep Snowpack; 1. Field Observations,
V84-01890 2C

Meltwater Movement in a Deep Snowpack; 2. imulation Model,
V84-01891 2C

OWPACK
Meltwater Movement in a Deep Snowpack; 1. Field Observations,
V84-01890 2C

Meltwater Movement in a Deep Snowpack; 2. imulation Model,
V84-01891 2C

Hydrometeorological Significance of Rime Ice Deposits in the Colorado Rockies,
V84-01948 2C

CIAL CHANGE
New Course for the Nile,
V84-02010 6G

Ten Years to Slake a Global Thirst,
V84-02011 6D

IL AGGREGATES
Effect of Crop Residue, Tillage-Induced Roughness, and Runoff Velocity on Size Distribution f Eroded Soil Aggregates,
V84-01877 2J

IL ANALYSIS
imple Determination of Oxime Carbamates in oil and Environmental Water by High Pressure iquid Chromatography,
V84-01861 5A

IL CONDITIONERS
Effect of Synthetic Conditioners on Soil Water Retention, Hydraulic Conductivity, Porosity nd Aggregation,
V84-01865 3F

IL DEPOSITION
Mathematical Model of Soil Erosion and Deposition Processes: I. Theory for a Plane Land Element,
V84-01874 2J

Mathematical Model of Soil Erosion and Deposition Processes: II. Application to Data from an Arid-Zone Catchment,
V84-01875 2J

IL EROSION
Relative Erodibility of 20 California Range and Forest Soils,
V84-01867 2J

Mathematical Model of Soil Erosion and Deposition Processes: I. Theory for a Plane Land Element,
V84-01874 2J

Mathematical Model of Soil Erosion and Deposition Processes: II. Application to Data from an Arid-Zone Catchment,
W84-01875 2J

Effect of Crop Residue, Tillage-Induced Roughness, and Runoff Velocity on Size Distribution of Eroded Soil Aggregates,
W84-01877 2J

Soil Erosion Awareness and Use of Conservation Tillage for Water Quality Control,
W84-01931 5G

Sediment Deposition Estimation from Cesium-137 Measurements,
W84-01938 2J

Predicting Erosion and Deposition on a Strip-mined and Reclaimed Area,
W84-01944 2J

SOIL INFILTRATION
Characterizing Unsaturated Hydraulic Conductivity of Western Kentucky Surface Mine Spoils and Soils,
W84-01872 2G

SOIL LOSS
Hydrology and Soil Loss from a High-Fertility, Rotational Pasture Program,
W84-01807 4C

SOIL POROSITY
Assessing the Suitability of Soils with Macropores for Subsurface Liquid Waste Disposal,
W84-01805 5D

SOIL PROPERTIES
Models for Estimating In-Situ Potential Extractable Water using Soil Physical and Chemical Properties,
W84-01869 2G

SOIL SATURATION
Soil Water Diffusivity Near Saturation,
W84-01864 2G

SOIL WATER
Passive Microwave Sensing of Soil Moisture Content: The Effects of Soil Bulk Density and Surface Roughness,
W84-01852 2G

In-Situ Determination of Soil Hydraulic Properties during Drainage,
W84-01862 2F

Soil Water Diffusivity Near Saturation,
W84-01864 2G

Effect of Synthetic Conditioners on Soil Water Retention, Hydraulic Conductivity, Porosity and Aggregation,
W84-01865 3F

Effect of Slope on Water Balance under Center-Pivot Irrigation,
W84-01868 2G

Field-Measured Limits of Soil Water Availability as Related to Laboratory-Measured Properties,
W84-01870 2G

Water Budget of an Eastern Deciduous Forest Stand,
W84-01871 2I

Soil Water Change as Related to Position of Wheat Straw Mulch on the Soil Surface,
W84-01873 3F

Stability Analysis of Water Movement in Unsaturated Porous Materials 2. Numerical Studies,
W84-01893 2F

Pulsed Trickling Effects on Soil Moisture Distribution,
W84-01946 3F

Model Study of the Short-Term Climatic and Hydrologic Effects of Sudden Snow-Cover Removal,
W84-02042 2A

SOIL WATER POTENTIAL
Water Budget of an Eastern Deciduous Forest Stand,
W84-01871 2I

SOLAR DISTILLATION
Recent Solar Distillation Developments,
W84-02095 3A

SOLUTE TRANSPORT
Theoretical Explanation of Solute Dispersion in Saturated Porous Media at the Darcy Scale,
W84-01887 2F

SOLVENT EXTRACTION
Effect of Organic Matter and Colloidal Particles on the Determination of Chromium(VI) in Natural Waters,
W84-02006 5A

SORPTION
PCB Partitioning in Sediment-Water Systems: The Effect of Sediment Concentration,
W84-01811 5B

Determination of Chromium(VI) in Natural Waters by the Sorption of Chromium-Diphenylcarbazone with XAD-2 Resin,
W84-02008 5A

SORPTIVITY
Calculation of Sorptivity from Constant-Rate Rainfall Infiltration Measurement,
W84-01863 2G

SOUTH AFRICA
Linear Organization of Localized Storms in the Summer Rainfall Zone of South Africa,
W84-02043 2B

SPATIAL DISTRIBUTION
Acid Rain Deposition Patterns in the Continental United States,
W84-02122 5B

SPECIES COMPOSITION
Problem of Classification of Acidified Watercourses (Zur Problematik der Gutebeurteilung von sauren Fliessgewassern),
W84-02069 5C

SPECTROPHOTOMETRY
Spectrophotometric Determination of Micro Amounts of Nitrite in Water and Soil,
W84-02004 5A

SPOIL BANKS
Characterizing Unsaturated Hydraulic Conductivity of Western Kentucky Surface Mine Spoils and Soils,
W84-01872 2G

SRI LANKA
Relationship Between Eastern Equatorial Pacific Sea Surface Temperatures and Rainfall over India and Sri Lanka,
W84-02044 2B

STATISTICAL ANALYSIS
Temporal Variations in Acid Precipitation over New York State-What the 1965-1979 USGS Data Reveal,
W84-01784 5B

Large Falls of Rain in Wales - a Simple Statistical Case Study,
W84-01988 2B

STATISTICAL METHODS
Statistical Estimation of Polynomial Generalized Covariance Functions and Hydrologic Applications,
W84-01884 2A

STORM RUNOFF
Upstream-Downstream: Rights and Responsibilities,
W84-01982 6E

STORM SEEPAGE
Mathematical Simulation of Interdependent Surface and Subsurface Hydrologic Processes,
W84-01892 2A

STRAW
Soil Water Change as Related to Position of Wheat Straw Mulch on the Soil Surface,
W84-01873 3F

STREAMFLOW
A Residual Noise Model for Streamflow Prediction,
W84-01983 2E

STREAMS
Continuous Ammonium Enrichment of a Woodland Stream: Uptake Kinetics, Leaf Decomposition, and Nitrification,
W84-01833 2H

Fish Communities Along Environmental Gradients in a System of Tropical Streams,
W84-01842 2H

Leaf Processing in Two Contrasting Beech Forest Streams: Effects of Physical and Biotic Factors on Litter Breakdown,
W84-01844 2H

STRESS ANALYSIS
Determination of Bulk Rock Properties from Ground-water Level Fluctuations,
W84-01813 2F

Stress and Seepage Analysis of Earth Dams,
W84-01959 8D

STRIP MINE WASTES
Characterizing Unsaturated Hydraulic Conductivity of Western Kentucky Surface Mine Spoils and Soils,
W84-01872 2G

STRIP MINES
Stream Water Quality of Two Small Watersheds as Affected by Surface Coal Mining,
W84-01809 5B

STRIPMINES
Predicting Erosion and Deposition on a Strip-mined and Reclaimed Area,
W84-01944 2J

STRONTIUM-90
Soda Ash Treatment of a Strontium-90-Contaminated Groundwater Seep,
W84-01810 5G

SUB-SAHARAN AFRICA
Sub-Saharan Rainfall in the Years 1976-80: Evidence of Continued Drought,
W84-02041 2B

SUBSIDENCE
Reconnaissance Estimates of Subsidence Along Salt-Gila Aqueduct, Arizona,
W84-01815 8D

Inexpensive Technique to Measure Subsidence Along Canals,
W84-01816 8D

Mathematical Model for Regional Land Subsidence Due to Pumping; 3. Integrated Equations for a Phreatic Aquifer,
W84-01883 2F

SUBSURFACE WASTE DISPOSAL
Assessing the Suitability of Soils with Macropores for Subsurface Liquid Waste Disposal,
W84-01805 5D

SULFATES
Determination of Chloride, Nitrate, Sulphate and Total Sulphur in Environmental Samples by Single-Column Ion Chromatography,
W84-02007 5A

SULFUR
Effect of Atmospheric Sulfur on the Composition of Three Adirondack Lakes,
W84-01976 5B

Determination of Chloride, Nitrate, Sulphate and Total Sulphur in Environmental Samples by Single-Column Ion Chromatography,
W84-02007 5A

SUPERSATURATION
Sensitivity of an Oligotrophic Lake Planktonic Bacterial Community to Oxygen Stress,
W84-02057 2H

SURFACE RUNOFF
Effect of Exchangeable Sodium and Gypsum on Surface Runoff from Loess Soil,
W84-01876 3F

Calibration of Snyder Coefficients for Pennsylvania,
W84-01949 2A

Dynamic Model for the Overland Flow on an Infiltrating Catchment,
W84-01994 2E

SURFACE WATER
Free and Forced Convection Effect on Evaporation,
W84-01967 2D

TAILWATER
Analysis of Dissolved Oxygen Concentrations in Tail Waters of Hydroelectric Dams and the Implications for Small-Scale Hydropower Development,
W84-01896 6G

TENAX
Analysis of Pesticides and Other Organic Pollutants by Preconcentration and Chromatographic Techniques,
W84-02120 5A

TERTIARY WASTEWATER TREATMENT
Phosphorus and Bacteria Elimination in a Sewage Treatment Plant with a Fourth Purification Stage (Weitestgehende Phosphor- und Bakterienentfernung in einer Klaranlage mit IV. Reinigungsstufe),
W84-02075 5D

TETRACHLOROETHYLENE
Tetrachloroethylene Contamination of Gr
water in Kalamazoo,
W84-01788

TEXAS
Source Contributions to Acid Precipitati
Texas,
W84-01783

TEXTILE MILL WASTES
Fouling Studies and Mathematical Modelli
Ultrafiltration of Textile Desizing Effluents,
W84-02106

TEXTILES
Studies on the Application of RO in Treat
of Rayon Plant Effluent,

THERMAL ENERGY STORAGE
Aquifer Thermal Energy Storage: An Att
to Counter Free Thermal Convection,
W84-01885

THERMAL PROPERTIES
Lake Temperature Dynamics in Hybrid Co
System,
W84-01772

THERMAL REGIME
Effects of Changes in pH on Transparency
Thermal Regimes of Lohi Lake, near Sudb
Ontario,
W84-01974

THERMAL STRATIFICATION
Comparison of the Formulation for Eddy D
sion in Two One-Dimensional Stratifica
Models,
W84-01995

THERMODYNAMIC EFFICIENCY
Exergetic Efficiency of MSF Process and
Conditions of Desalination by Waste Heat,
W84-02023

THERMOPLASTICS
Evaluation and Development of Techn
Thermoplastic Systems for Desalination
Other Water Treatment Applications,
W84-02031

THIN FILMS
Thermal Desalination of Sea Water in Thin
Plants,
W84-02092

THIN LAYER CHROMATOGRAPHY
One-dimensional Thin Layer Chromatograp
Separation and Fluorometric Quantification
Polycyclic Aromatic Hydrocarbons in W
Samples (Eindimensionale dunnschichtchro
tographische Trennung und fluorometris
Bestimmung von polycyclischen aromatisc
Kohlenwasserstoffen aus Wasserproben),
W84-02071

THROUGHFALL
Throughfall and Stemflow in the Forest Nu
ent Cycle,
W84-01987

THUNDERSTORMS
Heavy Thunderstorms Observed over Land
the Nimbus 7 Scanning Multichannel Mic
wave Radiometer,
W84-01857

TIDAL CHANNELS
Concentrations and Speciation of Lead, Zi
and Cadmium in Seawater-like Smelter Efflu
and Adjacent Marine Environments, Port Pi
South Australia,
W84-01838

LIBRARY U. OF I. URBANA-CHAMPAIGN

TILLAGE
Effect of Crop Residue, Tillage-Induced Roughness, and Runoff Velocity on Size Distribution of Eroded Soil Aggregates,
W84-01877 2J

TIME SERIES ANALYSIS
Trend Assessment of Water Quality Time Series,
W84-01937 5G

TOXICITY
Toxicity of Selected Priority Pollutants to Various Aquatic Organisms,
W84-01824 5C

Histological Observations in Gills of the Teleost Sarotherodon mossambicus with Reference to Mercury Toxicity,
W84-01825 5C

Acute Toxicity of Picric Acid and Picramic Acid to Rainbow Trout Salmo gairdneri, and American Oyster, Crassostrea virginica,
W84-01951 5C

Structure-Toxicity Relationships for the Fathead Minnow, Pimephales promelas: Narcotic Industrial Chemicals,
W84-01975 5C

Methods and Results Obtained from the Toxicological and Ecological Tests of Water Treatment Chemicals (Methoden und Ergebnisse bei der toxikologischen und okologischen Prufung von Wasserbehandlungsmitteln),
W84-02061 5F

Submerged Water Plants as Testing Organisms for Pollutants (Submerse Wasserpflanzen als Testorganismen fur Belastungsstoffe),
W84-02067 5A

Influence of Dissolved Oxygen Levels on Acute Toxicity of Phenolic Compounds to Fresh Water Telecost, Notopterus notopterus (Pallas),
W84-02117 5C

TRACE METALS
Stabilized Temperature Platform Furnace with Zeeman Effect Background Correction for Trace Analysis in Wastewater,
W84-01971 5A

TRANSPARENCY
Effects of Changes in pH on Transparency and Thermal Regimes of Lohi Lake, near Sudbury, Ontario,
W84-01974 2H

TREATABILITY
Contaminated Groundwater Treatability - A Case Study,
W84-01791 5F

TRICKLE IRRIGATION
Pulsed Trickling Effects on Soil Moisture Distribution,
W84-01946 3F

TROPHIC STATE
Trophic State Classification of Lakes with Aquatic Macrophytes,
W84-01981 2H

TROPICAL REGIONS
Pollution Levels in Some Nigerian Rivers,
W84-01905 5A

TROUT
Acute Toxicity of Picric Acid and Picramic Acid to Rainbow Trout Salmo gairdneri, and American Oyster, Crassostrea virginica,
W84-01951 5C

Zinc, Manganese, and Strontium in Opercula and Scales of Brook Trout (Salvelinus fontinalis) as Indicators of Lake Acidification,
W84-01980 5C

TURBIDITY
Role of Suspended Sediments in the Nutrition of Zooplankton in Turbid Reservoirs,
W84-01850 2H

TURBINES
Pumps that Play Turbines,
W84-01914 8C

TURBULENT FLOW
Turbulence Structure of Dilute Drag-Reducing Polymer Solutions in a Rectangular Open Channel Flow,
W84-02001 8B

TYPHOID FEVER
Movement of Typhoid Organisms in Saturated Permeable Soil,
W84-01787 5B

ULTRAFILTRATION
Fouling Studies and Mathematical Modelling of Ultrafiltration of Textile Desizing Effluents,
W84-02106 5D

UNIT HYDROGRAPHS
Calibration of Snyder Coefficients for Pennsylvania,
W84-01949 2A

URANIUM
Removing Uranium by Current Municipal Water Treatment Processes,
W84-01803 5F

VAPOR COMPRESSION
Operating Experience and Performance Data on an Advanced Barge-Mounted VTE/VC Seawater Desalination Plant,
W84-02032 3A

Comparative Study Between Vapor Compression and Multi Effect Boiling Desalination Systems,
W84-02035 3A

Computer Simulations of Multiple-Effect FFE-VC Systems for Water Desalination,
W84-02037 3A

VEGETATION MANAGEMENT
Water Yield Improvement Potential by Vegetation Management on Western Rangelands,
W84-01922 3B

VELOCITY
Effect of Crop Residue, Tillage-Induced Roughness, and Runoff Velocity on Size Distribution of Eroded Soil Aggregates,
W84-01877 2J

VERTICAL TUBE FOAM EVAPORATION
Operating Experience and Performance Data on an Advanced Barge-Mounted VTE/VC Seawater Desalination Plant,
W84-02032 3A

VERTICAL TUBE FOAMING EVAPORATOR
Desalting Water Costs Using Waste Heat from Power Systems Combined with the VTFE and Vapor Compression,
W84-02027 3A

WASH WATER
Application of IR-Spectroscopy in the Degradation of Organic Substances; Report III. Cation tensides (Einsatz der IR-Spektroskopie beim Abbau organischer Stoffe; III. Mitteilung: Kationtenside),
W84-02076 5D

WASHINGTON
Potential for Augmenting Water Yield Through Forest Practices in Western Washington and Western Oregon,
W84-01923 3B

WASTE WATER ANALYSIS
Chemical Oxidizability of Organic Water Pollutants (Chemische Oxidierbarkeiten organischer Wasserinhaltsstoffe (Ergebnisbericht)),
W84-02066 5A

WASTEWATER
Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments - V; Organic Carbons and Hydrocarbons in Sediments,
W84-01899 5A

WASTEWATER ANALYSIS
Stabilized Temperature Platform Furnace with Zeeman Effect Background Correction for Trace Analysis in Wastewater,
W84-01971 5A

Trace Determination of the Antihistamines Tripelennamine Hydrochloride, Thenyldiamine Hydrochloride, and Chlorothen Citrate in Admixture in Animal Feed, Human Urine, and Wastewater by High-Pressure Liquid Chromatography and Use of a Fluorescence Detector,
W84-02002 5A

WASTEWATER DISPOSAL
Protecting Water Supply Aquifers in Areas Using Deep-well Wastewater Disposal,
W84-01790 5G

WASTEWATER MANAGEMENT
Integrated Wastewater Management,
W84-01771 5D

Reducing Water Demand and Wastewater Flow,
W84-01796 3D

WASTEWATER REMOVATION
Reverse Osmosis Treatment and Reuse of Textile Dyehouse Effluents,
W84-02111 5D

WASTEWATER RENOVATION
Fouling Studies and Mathematical Modelling of Ultrafiltration of Textile Desizing Effluents,
W84-02106 5D

WASTEWATER TREATMENT
Anaerobic Biotechnology for Industrial Wastewater Treatment,
W84-01778 5D

Treatment of Low Strength Domestic Wastewater Using the Anaerobic Filter,
W84-01902 5D

Tertiary Treatment of Municipal Wastewater by Cypress Domes,
W84-01907 5D

Nitrification Back on Track,
W84-01913 5D

Waste Water Combustion in a Confined Swirl Flame,
W84-01993 5D

Wetlands for Wastewater Treatment,
W84-02000 5D

Wastewater Treatment - An Award-Winning System,
W84-02014 5D

Anaerobic Wastewater Treatment System Handles High-Strength Industrial Waste,
W84-02047 5D

Influence of Sewage Treatment and Urbanization on Selection of Multiple Resistance in Fecal Coliform Populations,
W84-02054 5B

Application of IR-Spectroscopy in the Degradation of Organic Substances; Report III. Cation tensides (Einsatz der IR-Spektroskopie beim Abbau organischer Stoffe; III. Mitteilung: Kationtenside),
W84-02076 5D

Application of Membrane Separation Processes to the Treatment of Industrial Effluents for Water Reuse,
W84-02110 5D

Make-Up Water Treatment at Thermal Power Plants and Multiple Waste Water Re-Use,
W84-02112 5D

Study of Emulsified Liquid Membrane Treatment of Phenolic Waste Water,
W84-02116 5D

WATER ALLOCATION
Multicriteria Analysis of Water Allocation in a River Basin: The Tchebycheff Approach,
W84-01879 6D

WATER ANALYSIS
Simple Determination of Oxime Carbamates in Soil and Environmental Water by High Pressure Liquid Chromatography,
W84-01861 5A

Spectrophotometric Determination of Micro Amounts of Nitrite in Water and Soil,
W84-02004 5A

Effect of Organic Matter and Colloidal Particles on the Determination of Chromium(VI) in Natural Waters,
W84-02006 5A

WATER AVAILABILITY
Field-Measured Limits of Soil Water Availability as Related to Laboratory-Measured Properties,
W84-01870 2G

WATER BUDGET
Water Budget of an Eastern Deciduous Forest Stand,
W84-01871 2I

WATER CHEMISTRY
Evaluation of Thermal Desalination Plants Water Chemistry,
W84-02104 3A

WATER COMSUMPTION
Alternative Structures for Water Rights Markets,

Chemistry of Reduced Sulfur Species and Their Removal from Groundwater Supplies,
W84-01792 5F

CHNABEL ENGINEERING ASSOCIATES, ETHESDA, MD.
Stress and Seepage Analysis of Earth Dams,
W84-01959 8D

CIENCE AND EDUCATION DMINISTRATION, COSHOCTON, OH.
Hydrology and Soil Loss from a High-Fertility, Rotational Pasture Program,
W84-01807 4C

Nitrogen Loss from a High-Fertility, Rotational Pasture Program,
W84-01808 5B

CIENCE AND EDUCATION DMINISTRATION, FORT COLLINS, CO. GRICULTURAL RESEARCH.
Mathematical Simulation of Interdependent Surface and Subsurface Hydrologic Processes,
W84-01892 2A

HAANXI MONITORING STATION OF NVIRONMENTAL PROTECTION, XIAN HINA).
Spectrophotometric Determination of Micro Amounts of Nitrite in Water and Soil,
W84-02004 5A

MITHSONIAN INSTITUTION, DGEWATER, MD. CHESAPEAKE BAY ENTER FOR ENVIRONMENTAL STUDIES.
Herbicide Runoff from Experimental Watersheds,
W84-01806 5B

OCIETE INTERNATIONALE DE ESSALEMENT, PARIS (FRANCE).
Application of the Multi-Effect Process at High Temperature for Large Seawater Desalination Plants,
W84-02036 3A

OUTHEASTERN FOREST EXPERIMENT ATION, ASHEVILLE, NC. COWEETA YDROLOGIC LAB.
Potential for Water Yield Augmentation from Forest Management in the Eastern United States,
W84-01920 3B

OUTHERN CALIFORNIA METROPOLITAN ATER DISTRICT, LA VERNE. WATER UALITY BRANCH.
Optimizing Large-Scale Water Treatment Plants for Asbestos-Fiber Removal,
W84-01801 5D

OUTHERN ILLINOIS UNIV. AT RBONDALE. DEPT. OF FORESTRY.
Calculation of Sorptivity from Constant-Rate Rainfall Infiltration Measurement,
W84-01863 2G

I VENKATESWARA UNIV., TIRUPATI NDIA). DEPT. OF ZOOLOGY.
Histological Observations in Gills of the Teleost Sarotherodon mossambicus with Reference to Mercury Toxicity,
W84-01825 5C

STADTWERKE MAINZ A.G. (GERMANY, F.R.).
Simple Method for Determining the Catalase Activity in Sludge, Sediment, and Water (Ein einfaches Verfahren zur Bestimmung der Katalase-Aktivitat in Schlammm, Sediment und Wasser),
W84-02073 5A

STANDARD OIL CO. (OHIO), CLEVELAND.
Treatment of Low Strength Domestic Wastewater Using the Anaerobic Filter,
W84-01902 5D

STANTON AND STAVELEY LTD., NOTTINGHAM (ENGLAND).
Development of Protection Systems for Buried Ductile Iron Pipes,
W84-02018 8G

STEVENS INST. OF TECH., HOBOKEN, NJ. DEPT. OF CHEMISTRY AND CHEMICAL ENGINEERING.
Short Cut Design Methods for Reverse Osmosis Separation with Tubular Modules,
W84-02098 3A

STEWARTS AND LLOYDS PLASTICS, HUNTINGDON (ENGLAND).
Polyethylene Piping Systems for Use in the Water Industry,
W84-02020 8F

STICHTING VOOR BODEMKARTERING, WAGENINGEN (NETHERLANDS).
Assessing the Suitability of Soils with Macropores for Subsurface Liquid Waste Disposal,
W84-01805 5D

STRATHCLYDE REGIONAL COUNCIL, GLASGOW (SCOTLAND). WATER DEPT.
Seagull Pollution of Reservoirs,
W84-01823 5B

Contamination of a Major Water Supply by Gulls (Larus sp.); A Study of the Problem and Remedial Action Taken,
W84-01897 5C

SWCC AL-KHOBAR DESALINATION PLANT (SAUDI ARABIA).
Simulation of M.S.F. Desalination Plants,
W84-02034 3A

TECHNICAL UNIV. OF NOVA SCOTIA, HALIFAX. DEPT. OF CIVIL ENGINEERING.
Upstream-Downstream: Rights and Responsibilities,
W84-01982 6E

TECHNION - ISRAEL INST. OF TECH., HAIFA.
Phosphorus and Calcium Carbonate Solubilities in Lake Kinneret,
W84-01836 2H

TECHNISCHE HOCHSCHULE, AACHEN (GERMANY, F.R.). INST. FUER VERFAHRENSTECHNIK.
Assessment of Different Scale Control Methods,
W84-02103 3A

TECHNISCHE HOCHSCHULE, DARMSTADT (GERMANY, F.R.). INST. FUER WASSERVERSORGUNG, ABWASSERBESEITIGUNG UND RAUMPLANUNG.
Numerical Examination of the Elution of Aquatic Sediments (Rechnerische Behandlung der Elution von Sedimenten),
W84-02068 2K

TECHNISCHE HOGESCHOOL, DELFT (NETHERLANDS). DEPT. OF CHEMICAL ENGINEERING AND CHEMISTRY.
Prevention of Calcium Sulfate Scale Deposition by a Fluidized Bed,
W84-02100 3A

TECHNISCHE HOGESCHOOL, DELFT (NETHERLANDS). DEPT. OF CIVIL ENGINEERING.
Main Flow Velocity in Short River Bends,
W84-01964 8B

TECHNISCHE UNIV., MUNICH (GERMANY, F.R.). INST. FUER WASSERCHEMIE UND CHEMISCHE BALNEOLOGIE.
Formation of the Bromine-Containing Trihalomethane in Water, Its Prevention and Possibility of Elimination; Part I: Determination of Bromide and Iodide in Low Concentration (Bildung bromhaltiger Trihalomethane im Wasser, ihre Verhinderung und Moglichkeiten der Elimination; I. Mitt: Bestimmung von Bromid und Iodid in Spurenkonzentrationen),
W84-02065 5A

TENNESSEE UNIV., KNOXVILLE. DEPT. OF MICROBIOLOGY.
Microcosm and Experimental Pond Evaluation of Microbial Community Response to Synthetic Oil Contamination in Freshwater Sediments,
W84-02053 5C

Degradation and Total Mineralization of Monohalogenated Biphenyls in Natural Sediment and Mixed Bacterial Culture,
W84-02060 5B

TETRA TECH, INC., PASADENA, CA.
Flow Depth in Sand-Bed Channels,
W84-01963 8B

TEXAS A AND M UNIV., COLLEGE STATION. DEPT. OF AGRICULTURAL ECONOMICS.
Enhanced Role of Water Conservation in the Cost-Benefit Analysis of Water Projects,
W84-01930 6B

TEXAS A AND M UNIV., COLLEGE STATION. DEPT. OF GEOLOGY.
Determination of Bulk Rock Properties from Ground-water Level Fluctuations,
W84-01813 2F

TEXAS AGRICULTURAL EXPERIMENT STATION, COLLEGE STATION.
Models for Estimating In-Situ Potential Extractable Water using Soil Physical and Chemical Properties,
W84-01869 2G

Field-Measured Limits of Soil Water Availability as Related to Laboratory-Measured Properties,
W84-01870 2G

TEXAS AGRICULTURAL EXPERIMENT STATION, COLLEGE STATION. DEPT. OF RECREATION AND PARKS.
Ex Post Facto Analysis of the Regional Economic Impact of Expenditures for Reservoir Recreation,
W84-01829 6G

TEXAS UNIV. AT AUSTIN. ENVIRONMENTAL HEALTH ENGINEERING GROUP.
Source Contributions to Acid Precipitation in Texas,
W84-01783 5B

THESSALONIKI UNIV., SALONIKA (GREECE). LAB. OF HYDRAULICS AND HYDRAULIC WORKS.
Modelling of Discontinuities Through Dipole Distribution,
W84-01997 8B

TIANJIN UNIV. (CHINA). DEPT. OF CHEMICAL ENGINEERING.
Exergetic Efficiency of MSF Process and the Conditions of Desalination by Waste Heat,
W84-02023 3A

TOKYO METROPOLITAN UNIV. (JAPAN). DEPT. OF CHEMISTRY.
Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments - V; Organic Carbons and Hydrocarbons in Sediments,
W84-01899 5A

TRENT UNIV., PETERBOROUGH (ONTARIO).
Anthropogenic Zinc and Cadmium Burdens in Sediments of Selected Southern Ontario Lakes,
W84-01973 5B

TUV STUTTGART E.V., FILDERSTADT (GERMANY, F.R.).WARNETECHNIK UND UMWELTSCHUTZ.
Submerged Water Plants as Testing Organisms for Pollutants (Submerse Wasserpflanzen als Testorganismen fur Belastungsstoffe),
W84-02067 5A

UNIVERSIDAD CENTRAL DE VENEZUELA, CARACAS. FACULTAD DE INGENIERIA.
Flow in Alluvial-River Curves,
W84-01851 2E

UNIVERSITY OF PETROLEUM AND MINERALS, DHAHRAN (SAUDI ARABIA).
Desalination of Water in Saudi Arabia by Reverse Osmosis, Performance Study,
W84-02078 3A

UNIVERSITY OF WESTERN ONTARIO, LONDON. DEPT. OF STATISTICAL AND ACTUARIAL SCIENCES.
Trend Assessment of Water Quality Time Series,
W84-01937 5G

UPPER OCCOQUAN SEWAGE AUTHORITY, CENTREVILLE, VA.
Tight Effluent Specs Met with Digital Control,
W84-01919 5D

UPSTATE FRESHWATER INST., SYRACUSE, NY.
Onondaga Lake and Dissolved Oxygen in Seneca River,
W84-01957 5C

URS CO., LAS VEGAS, NV.
Water for Las Vegas Metropolitan Area,
